AN ECONOMIC EVALUATION OF PREMIUM VINEYARDS AND WINERIES IN ARIZONA (VITICULTURE, ENOLOGY)

INFORMATION TO USERS

This reproduction was made from a copy of a document sent to us for microfilming. While the most advanced technology has been used to photograph and reproduce this document, the quality of the reproduction is heavily dependent upon the quality of the material submitted.

The following explanation of techniques is provided to help clarify markings or notations which may appear on this reproduction.

1. The sign or "target" for pages apparently lacking from the document photographed is "Missing Page(s)". If it was possible to obtain the missing page(s) or section, they are spliced into the film along with adjacent pages. This may have necessitated cutting through an image and duplicating adjacent pages to assure complete continuity.

2. When an image on the film is obliterated with a round black mark, it is an indication of either blurred copy because of movement during exposure, duplicate copy, or copyrighted materials that should not have been filmed. For blurred pages, a good image of the page can be found in the adjacent frame. If copyrighted materials were deleted, a target note will appear listing the pages in the adjacent frame.

3. When a map, drawing or chart, etc., is part of the material being photographed, a definite method of "sectioning" the material has been followed. It is customary to begin filming at the upper left hand corner of a large sheet and to continue from left to right in equal sections with small overlaps. If necessary, sectioning is continued again–beginning below the first row and continuing on until complete.

4. For illustrations that cannot be satisfactorily reproduced by xerographic means, photographic prints can be purchased at additional cost and inserted into your xerographic copy. These prints are available upon request from the Dissertations Customer Services Department.

5. Some pages in any document may have indistinct print. In all cases the best available copy has been filmed.

1987

STATEMENT BY AUTHOR

This thesis has been submitted in partial fulfillment of requirements for an advanced degree at the University of Arizona and is deposited in the University Library to be made available to borrowers under rules of the library.

Brief quotations from this thesis are allowable without special permission, provided that accurate acknowledgement of source is made. Requests for permission for extended quotation from or reproduction of this manuscript in whole or in part may be granted by the head of the major department or Dean of the Graduate College when in his or her judgement the proposed use of the material is in the interests of scholarship. In all other instances, however, permission must be obtained from the author.

Signed: Thomas a. Brady jr.

APPROVAL BY THESIS DIRECTOR

This thesis has been approved on the date shown below:

Paul N. Wilson — May 4, 1987

Dr. Paul Wilson — Date

Professor of Agricultural Economics

ACKNOWLEDGEMENTS

Robert de Treville Lawrence and the Vinifera Wine Growers Association provided the initial impetus for my interest in vineyard and winery economics. I'm grateful to Dr. Jimmye Hillman, Dr. Roger Fox, and Dr. Robert Firch for their efforts in securing a position for me as a research-assistant in the Agricultural Economics Department.

The insights and enthusiasm that Dr. Wilson contributed to this study were of the highest order and indispensable. Dr. Merle Faminow, and Dr. James Wade collaborated on the research and are also thanked. Special acknowledgement goes to Dr. Gordon Dutt, the harbinger of the the Arizona wine industry.

Computer assistance provided by Mrs Annie Hudecek permeates this entire manuscript. Thank You.

Direct or indirect contributions were made by Dr. Eugene Mielke, Dr. Mike Kilby, Dr. Robert Angus, Adrian Bosman, Robert Webb, Roger Coupal, Teddy Goldammer, Burton Kaufer, and Walter Slipp.

My wife Susan introduced me to winegrowing, and she earns the bulk of the accolades for her support and encouragement. Thank you Tommy and Katie Brady and Mr. and Mrs John Reichhardt and Mr. and Mrs Thomas Brady.

ABSTRACT

Economic and financial analysis is conducted on small, premium vineyards, wineries and joint vineyard and wineries in Arizona. The vineyards range in size from twenty acres to one hundred acres, and the wineries from twelve thousand gallons to sixty thousand gallons. The objectives are to estimate the potential demand for Arizona wine, construct budgets for winegrowing enterprises, and evaluate the economic and financial profitability varying interest rates, prices of grapes, and receipts. Results indicate favorable conditions for the establishment of an indigenous wine industry. Small vineyards and wineries can be profitable, especially when economies of size are gained and strong retail sales are established.

CHAPTER ONE

INTRODUCTION

Viticulture was brought to the western shores of the Americas by Spanish conquistadors. As the unexplored frontiers were pushed back, grape culture advanced. During the seventeenth and eighteenth centuries the spread of grape and wine production in western North America was largely associated with the Catholic Church. Early in the nineteenth century the Spanish missions had increased contact with the rest of the world as ships began to stop frequently at Californian ports. This greatly augmented the facilities for wine production in that state. Commercial and private plantings of vines began in earnest in the 1820's and prospered until national Prohibition thoroughly disrupted the industry a century later (Adams, 1973).

Repeal of Prohibition, in 1933, occurred in the midst of the great Depression, and winegrowing in America was slow to rebound. Although per capita wine consumption was more than six gallons annually in 1920, before Prohibition, it took decades for consumption to climb back over one gallon after Repeal. In the 1940's, 1950's, and most of the 1960's, the predominant types of wine sold in North America were sweet dessert wines and "pop" wines which were artificially

flavored, low alcohol varieties with perceptible residual sugar. In the mid-1960's the United States, led by California, entered into an unprecedented wine boom based on premium European classic grape cultivars such as Chardonnay and Cabernet Sauvignon. By 1968, table wines had surpassed dessert wines in total sales. In 1972, per capita wine consumption in the U.S. increased to over two gallons. In 1982, total wine sales out-stripped total hard spirits sales in the United States for the first time. In 1985, wine sales, including wine coolers, were up 4.1% to 577.2 million gallons. For the entire post prohibition era (1934-1985) sales of wine grew at an annual rate of 5.8%, increasing from 32.7 million gallons to 577.2 million gallons. Per capita wine consumption grew from 2.34 gallons in 1984 to 2.42 in 1985 for a 3.4% increase (Wines and Vines Statistical Issue, July 1986). Between 1975 and 1980 the number of bonded wineries in the United States grew from 569 to 822. From 1980 to 1985, 467 more premises were added for a total of 1,289. Half the growth in wineries occurred outside of California. Forty-one states possessed at least one bonded winery (TABLE 1).

ARIZONA WINEGROWING

The history of viticulture in Arizona reflected the relatively slow development of this State and the difficult agricultural obstacles indigenous to the region. A few

scattered efforts were made to grow wine grapes in central Arizona in the latter decades of the nineteenth century, but most of the natural areas for such an endeavor in southeastern Arizona were under control of hostile Apaches. In the early decades of the twentieth century Prohibition halted any serious commercial ventures.

The University of Arizona became interested in wine grape growing in the early 1970's as a by-product of a water harvesting project. The water conservation research was aimed at watering crops solely from rainfall using contours and terraces. It was found that grapes required half the water per acre of some of Arizona's traditional crops like cotton and alfalfa, and the wines produced by the fruit were of surprisingly consistent high caliber. A number of experimental vineyards were planted around the state, including one on the Babocomari Ranch near Sonoita in Southeastern Arizona. A University winery was set up to evaluate the wines. The results of the research were coupled with similar data from New Mexico, Colorado, and Utah, and were published in 1980 (Dutt, 1980). The conclusion for Arizona, especially at higher elevations, was that there was good potential to produce fine, premium quality vintage wines from the classic Vitis Vinifera grape varieties.

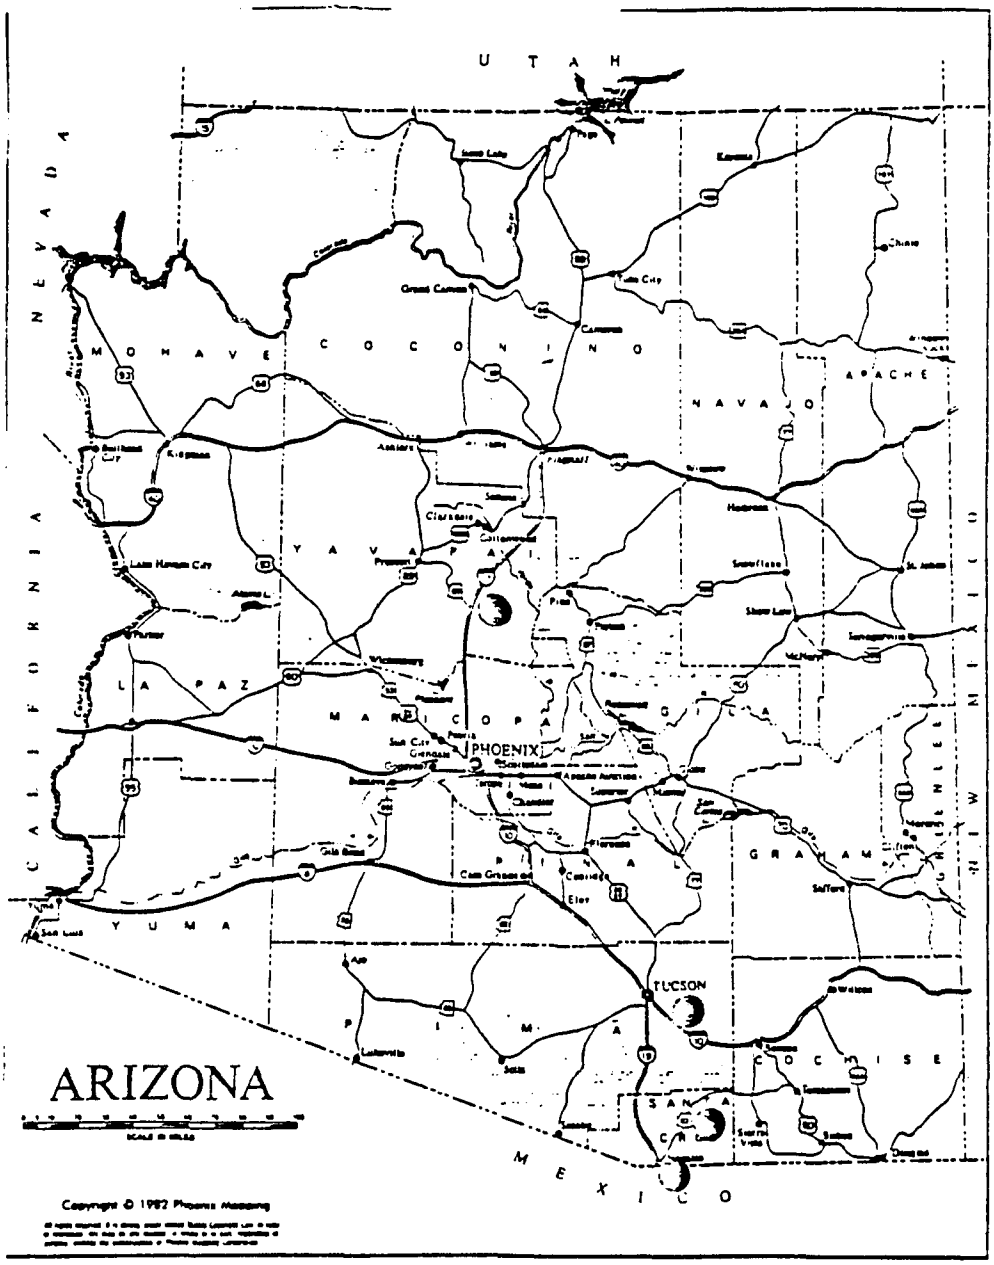
In 1980 Arizona's first new bonded winery, located in Tucson, released wines produced in Arizona made from fruit from California and Mexico. In 1981, an Arizona Wine Growers

Association was formed which lobbied successfully for the passage of a State Farm Winery Bill which recognized wine as an agricultural product and reduced taxes on Arizona wine, in addition to allowing for direct retail sales at state wineries (Appendix A). In 1984 two additional bonded wineries, established in Sonoita and in the Verde Valley north of Phoenix, released Arizona wines produced from Arizona fruit. In 1984 the Sonoita Viticultural Area became Arizona's first federally created appellation of origin district (Appendix B). An annual wine festival was inaugurated in Sonoita that same year. In 1985 a fourth bonded winery opened outside of Nogales (Figure 1). In 1986 the first Arizona Wine Competition was held in conjunction with the Third Sonoita Wine Festival, and The Arizona Wine Journal began publication. From 1980 to 1986 approximately 150 acres of premium wine grapes were planted in Arizona, mostly concentrated in the southeastern portion of the state at elevations between 4,000 and 5,000 feet. In 1987 approximately 100 acres of wine grapes are expected to be planted in Arizona.

SONOITA

The first recognized winegrowing region in Arizona is Sonoita. The bulk of the fine wine grapes grown in Arizona in 1986 and planted in 1987 are in Sonoita. This paper will use the Sonoita area as a basis for a case study

Figure 1. Locations of Arizona's Four Bonded Wineries.



on Arizona winegrowing.

The Sonoita Viticultural District is the focal point of the present wine industry for a number of reasons. It is located sixty miles southeast of Tucson in a popular historic setting. The area was first explored in 1539 by Fray Marcos de Niza, a Franciscan, whose fanciful report of finding the mythical Seven Cities of Cibola soon brought Francisco Vasquez de Coronado to the land searching for wealth and glory. The first real settlement by non-Indians came in 1691 when Padre Eusebio Francisco Kino, a Jesuit missionary-explorer, established a visita for the Sobaipuri Indians. The visita was called Los Santos Reyes de Sonoita. The area was slow to develop, primarily because it was in the center of Apache controlled lands. The Gadsen Purchase of 1853 secured this territory for the United States. The area is classified as "high desert grassland" and is surrounded on all sides by mountains which are part of the Coronado National Forest. It is zoned for agricultural use. Sonoita is outside of the Tucson Active Management Area, and is therefore not subject to the moratorium established by the 1980 Groundwater Management Act, which prohibits new irrigated agricultural acreage in active management areas (Richardson, 1971).

The primary soil association for the Sonoita area is a combination of Bernadino-Hathaway-White House gravelly loam. This series of soils can be more than sixty inches deep on

slopes ranging from 0 to 10 degrees. The soils are formed in old alluvium from igneous and calcareous sedimentary rocks. Grape vines are deep rooted plants that require good water drainage and light to medium soil fertility. These soils provide both. Average annual precipitation for the region is approximately 18 inches. The mean annual temperature is around 60 degrees Fahrenheit. The frost free season is over 200 days (Richardson, 1971). The high altitude of Sonoita allows for cooler average temperatures which slow ripening of fruit and aid in producing a balance between acid, which gives wine body, and sugar, which is fermented into alcohol. On cold nights late in the spring or early in the fall, the cooler air will tend to journey down the broad slopes while the warmer, less dense air will rise up the plains, thereby affording a degree of protection for the vines planted on hill sides. Water runoff is slow and the hazard of erosion is slight. The soils have moderate to high available water capacity, which contributes to good drainage. Current vegetation is mainly grasses and forbs, and historically the land has been used for grazing livestock and wildlife. The natural attractiveness of the area, the horse races and restaurants in Sonoita, the lakes and mountains of the Coronado Forest, the popularity of nearby towns like Patagonia and Tombstone, and the proximity of Tucson, all combine to make the location a reasonable choice for

wineries that are predicated on strong tourist traffic and on-site retail sales (Figure 2).

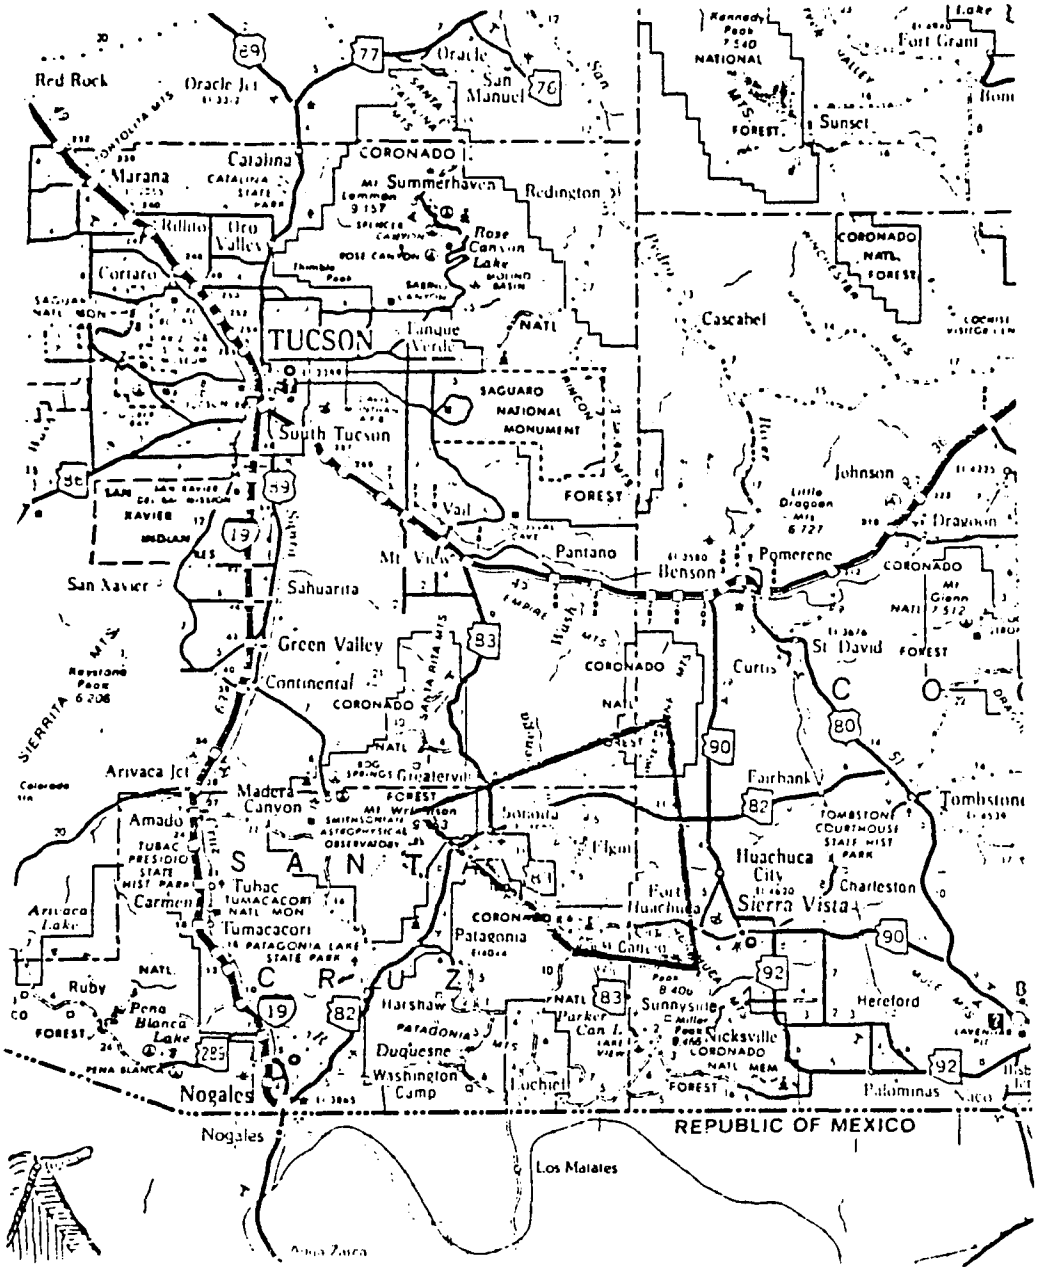
Other Arizona areas that wine vineyards are being planted in, include the Sulphur Spring Valley in Cochise County south of Wilcox, the area surrounding Bonita in Graham County, the southern slopes of the Rincon Mountains between Vail and Benson, and the Verde Valley north of Phoenix. It is the author's opinion that many more micro-districts exist in Arizona that have yet to be used for viniculture. An unscientific method of finding potential sites is to locate in areas where apples can be successfully grown. Apples blossom before grapes and are exposed to the dangers of frost earlier. If apples can thrive in a locale then it is reasonable to surmise that wine grapes would also flourish.

RISKS

Agricultural risks involved in growing premium wine grapes in Arizona are varied. Vitis Vinifera grape vines are hardy plants which have adapted to harsh enviroments around the world. They can withstand a series or combination of inflictions with minimal fruit loss. However, the possibility always exists that a particularly unfortunate set of disorders could occur, resulting in severe crop loss or extensive vine damage.

The most important disease of grapevines in the

Figure 2. The Sonoita Viticultural Area.



Southwest is a fungus called Texas Root Rot (Phymatotrichum omnivorum). The symptoms of the disease is prevalent during the warm months of June through September and it will penetrate the outer living tissue of grapevines and destroy the roots. Should the crown of the root be attacked, death of the vine will ensue. Badly infected vines show a great deal of defoliation, dead wood, decayed roots and raisined clusters. There are two treatments available if the problem does appear, both are expensive. One method of solving the problem is to apply sulfur to the soil to lower the pH, in order to control the growth of the rot. An alternative if the rot is suspected is to use grafted vines with a resistant rootstock in future plantings. Neither practice is totally effective. The only sure way to avoid the disease is to select a vineyard site that is root rot free (Dutt, 1980).

Two other fungal diseases that pose a more certain, but less serious challenge, are Powdery Mildew and Bunch Rot. They both lower fruit quality by causing the berries to prematurely decay. Sulfur dust sprays are the most effective means of controlling these diseases. Other potential problems are leafroll, yellow mosaic, corky bark and yellow vein. These infections tend to reduce the general vigor of the vines and fruit production. The best control over these irritants is to insure that only certified, virus-free rootings are planted in the vineyard.

A variety of insect pests exist in Arizona that cause concern for grapegrowers. They include the flea beetle, grape leaf hopper, grape leaf folder, the western grapeleaf skeletonizer and possibly phylloxera. Most of these destroy buds, young leaves, tendershoots or fleshy root tissue. The usual remedy for these threats takes the form of sprays that won't enter or can be filtered out of wine. Other pests that most surely will be encountered in Arizona vineyards, with varied detrimental impacts, will be birds, deer, rabbits, mice, gophers and tourists. These are potentially serious causes of grape losses and tender shoot damage. A couple of good vineyard dogs, or noise-making carbide cannons are recommended to keep these pests at bay.

Weather injury from hail, lightning, excessive heat, early and late frosts and severe winter cold will be constant threats to Arizona vineyards. There are several weeks at a time when one or several of these problems will be a major concern. An untimely hail at flowering or just before harvest could reduce potential or actual production. Lightning has been known to hit a trellis wire and wipe out an entire row of vines. Excessive heat may cause an early ripening, reducing acid and fruit balance. Frosts in the spring can damage young shoots and in the fall can destroy late ripening fruit and the following year's fruiting canes. A severe winter also can impair potential production by

hurting dormant buds and wood.

While the list of potential agricultural dangers for winegrowers seems extensive, there is little evidence that viniculture in Arizona poses more problems than other fine wine growing districts around the world. The list of viticultural concerns faced in other regions, but not posed in Arizona is more extensive than the threats listed for this state. The salient point here is that other established winegrowing regions have a history and therefore a record of dealing with their agricultural idiosyncrasies, in Arizona the labor has just begun.

THE MARKET

Total wine consumption in Arizona in 1985 was 8,983,000 gallons, up from 8,215,000 in 1984, Arizona produced roughly 0.002% of its own consumption in state bonded wineries, the balance was imported from out of state (author's calculations). Currently the four bonded wineries in Arizona have a combined capacity of 44,000 gallons. Total actual production in 1986 will be half that figure. Most of the wines produced in Arizona will be made from Arizona grown fruit, however these will be comprised largely from lesser table varieties rather than fine wine grapes. None of the estimated 150 acres of fine wine vineyards in Arizona have reached full maturity.

Viniculture in Arizona presents some unique

opportunities for marketing. There are three main varieties of grapes grown in the United States for table wines: native American grapes, French-American hybrids, and European Vitis Vinifera. American grape varieties such as Concord, Catawba, Delaware and Niagara are big producers with immunity to many pests and diseases. Their fruit has a distinctive " Welch's grape" flavor that one would associate with grape soda pop or grape chewing gum. The grape can be vinified into sweet dessert wines and have been for years. Unfortunately, the grapy flavor that is so characteristic of the fruit, when vinified dry, becomes harsh and dominates. This "foxy" flavor has been rejected by wine drinkers, and so American varieties are seldom used for dry wines. The growth of the dry table wine market at the expense of sweet wines has hurt traditional grape growing areas, mainly in the east and south, that have relied on these varieties (Adams, 1973).

The French hybrids were created by a catastrophe in the vineyards of Europe during the latter parts of the 19th century. In the 1860's an aphid native to the United States was exported to France on some grapevine cuttings. This louse attacked the root systems of vines, eventually killing them. The European vines have fleshy roots and are especially susceptible to an attack by phylloxera. American varieties have a woody, more fibrous system and some natural immunity. By the 1880's virtually all the vineyards of Europe had been hit by the pest, with up to 90% of the vines

destroyed. One solution to the problem was to cross breed American varieties with European varieties in order to produce vines that had immunity to phylloxera coupled with good, traditional fruit. The hybrids that resulted are currently being planted extensively in the east and mid-west United States because they have good winter hardiness, immunity to phylloxera and produce wines akin to the European varietals (Wagner, 1965). The general criticism of hybrids is that, while they produce good wines, they are incapable of producing great wines.

The great wines of the world are produced by the European species Vitis Vinifera. Phylloxera spread virtually all over the wine-growing world and, ironically, made its way west of the Rockies into California on vines imported from France. The alternative solution to the use of hybrids in combating phylloxera and the one employed in France, Europe and California, was to graft the European scion onto native American root stock. This provided immunity to the aphid and allowed the use of the classic fruit for vinification. Today most of the premium wine vineyards of the world are grown on American root stock (Winkler, 1974).

A few eco-niches exist that have escaped the phylloxera infestation. The Andes have protected Chile. Parts of Australia, South Africa and even California have been spared. The southwestern desert of the United States has

proven so far to be too hot for the pest. The Sonoita "appellation of origin" district is one of those rare areas where classic Vinifera varieties will thrive on their own roots and may produce distinctively varietal wines which will display the nuances of pre-phylloxera vintages.

Vintage dates on labels also add value to wines. The vintage label applies to the year the fruit was harvested. Wines made from the fruit of one vintage year are considered special for the mystique of tasting a summer a few or many years past. Boutique or small wineries in approved appellation regions commonly produce premium table wines using the estate bottled, varietal, and vintage date designations. Estate bottled wines are wines made exclusively from grapes grown in vineyards that are in federally recognized viticultural districts. Varietal wines contain at least 75% of one grape variety such as Sauvignon Blanc. Vintage wines are vinified from fruit gathered in the same harvest year. These compare favorably to ordinary table wines that are often made from the fruit from many vineyards in different areas, blended with a variety of grapes from several vintage years. The designation of Sonoita as a recognized viticultural district creates the potential for wines with the estate bottled label to be produced in Arizona.

In the last fifteen to twenty years there have been major strides made in the technology of winemaking. Much of

it has originated in California. The trends have been toward wines that are not big and alcoholic, but rather light with the emphasis on fruit and varietal character. The greatest single radical change that has been adopted in wineries has been the use of stainless steel refrigeration tanks. This allows the winemaker complete control over temperature and fermentation. Subtle, easily dissipated flavors are more readily retained under controlled conditions. Advances in yeast strains, filtration, lab monitoring procedures and oxygen control during bottling have also contributed to clean, crisp, consistent wines. Most of these changes have been exogenous in nature. The endogenous, ages old process of yeast acting on grape sugar and converting it to alcohol and free CO2 continues as always. The upshot of these technological advances is that relatively young wineries employing these new concepts can be extremely competitive in wine quality. The possibility exists for Arizona to produce high standard wines in a short period by embracing the latest procedures.

OBJECTIVES

The general objective of this work is to determine the economic feasibility of small, premium, vineyard and winery investments in Arizona. The procedure is to estimate the costs and returns from three different sized vineyards and farm wineries based on various assumptions regarding input

costs, output prices and the Arizona market. The specific objectives of this study were to:

1. Determine the total investment costs of establishing and maintaining three different sized vineyards;
2. Determine the total investment costs of building and operating three different sized wineries;
3. Determine the total investment and operating costs of the three different sized vineyards combined with their appropriate sized wineries.
4. Estimate the annual cash flow for each vineyard and each winery, and each vineyard combined with its appropriate sized winery.
5. Evaluate the potential market for Arizona wines in Arizona.
6. Determine the impact of various alternative assumptions concerning input costs, product mix and output prices on the profitability of the investments using net present value and internal rate of return analysis.

CHAPTER TWO

LITERATURE REVIEW

A small amount of data have been generated on the economics of combined vineyard and winery ventures in the United States. No in-depth studies have been made on the two facets of winegrowing in Arizona. A considerable amount of literature has been published nationwide pertaining to the economics of vineyards and a more limited output of research is available on winery budgets. The following is a general literature review of the economic considerations pertaining to the viticultural, enological, and marketing aspects of winegrowing.

VINEYARD SITE SELECTION

Site selection is the initial concern in establishing a premium wine vineyard. Technical Bulletin 239 published by the University of Arizona as part of the Four Corners Regional Commission's research into grape and wine production, Dutt (1980), attempted to delineate the grape growing areas in the Four Corners Region. These ranged from the hot low deserts of Arizona and New Mexico to the cool high valleys of Colorado and Utah. Arizona was a Zone V according to the California base 50 growing-degree-day (G.D.D.) model. The G.D.D. method wasdevelopedto aid in

determining varietal suitability for a given location. The G.D.D. calculates the heat summation units of a region. The approximate temperature at which vine growth begins is 50 degrees F. which is the temperature base. Heat summation refers to the sum of the mean monthly temperature above 50 degrees F. for the period concerned. The summation is expressed as degree-days. Areas are segregated into five grape producing regions when the total degree days are calculated. The climatic districts are:

TABLE 2

Region	Growing Degree Days
I	less than 2,500
II	2,501 to 3,000
III	3,001 to 3,500
IV	3,501 to 4,000
V	over 4,001

A region V has the hottest climate of the areas that can produce grapes and is generally not recommended for premium wine varieties. It is well suited for table grapes. The Four Corners study developed a new model for delineation of viticultural zones. It was found that a model based on soil surveys and altitude allowed for wider climatic conditions to be evaluated in making varietal recommendations and predicting wine quality. The study concluded that at altitudes above 4,000 feet where thermic soils are found and good air drainage exists, premium white

and red table wine varieties could be grown. The significance of the research was that it challenged the assumption that Arizona was to hot for wine grape production.

The Four Corners report noted that the most important consideration for developing a successful grape vineyard was the selection of the vineyard site and the grape varieties planted. Site selection based on mean minimum and recorded maximum temperatures, rainfall, growing season length and heat summation provides little empirical data for varietal selection. The Four Corners model attempted to take the major selection criteria away from the growing degree day concept and placed it on soil characteristics. Soils considered for wine grape production should be low in organic matter and permeable with good drainage. They should be hyperthermic, thermic or lower mesic, which means the mean annual temperature at a 50 cm depth should be greater than 47 degrees F. Success in matching regions to varieties will be one of the primary viticultural concerns in Arizona for decades to come.

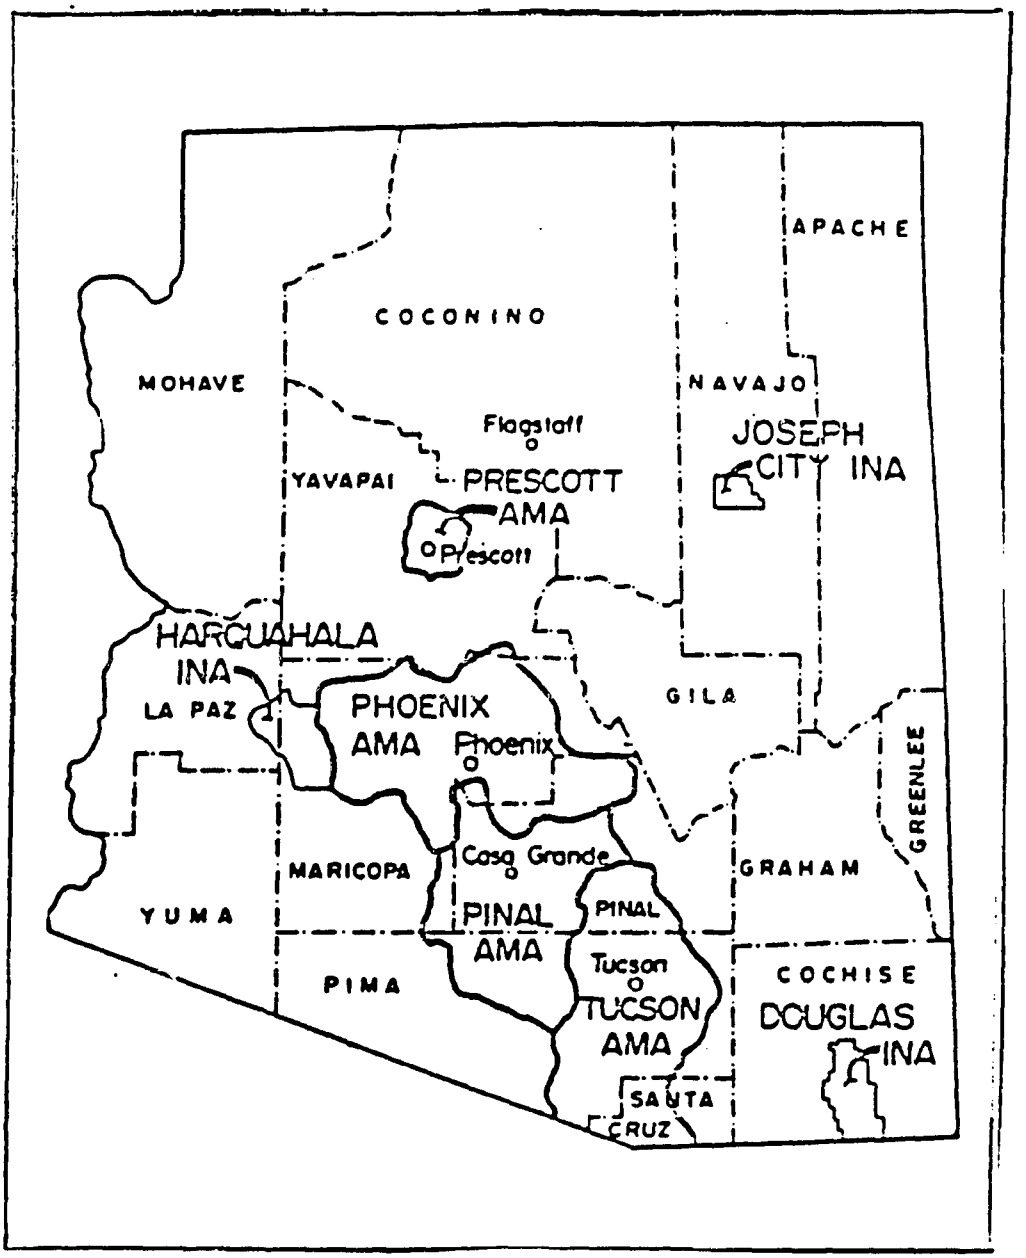
Savage and Hamman (1984) found in a study in Colorado that the price of land was the most important financial factor in vineyard investment and would probably determine the economic feasibility of a vineyard regardless of other costs. Price is viewed as the primary criteria for site selection. Winkler (1974) stated that temperatures and

exposures were the first considerations in site selection, followed by the amount, nature and season of rainfall, prevailing winds, soil conditions and the presence of specific wine pests or diseases. In Arizona the availability of water is of paramount concern. The vineyard site selection process must take into consideration the 1980 Groundwater Management Act, which limits irrigated agricultural acreage in active management districts (Figure 3). Careful attention must also be given to elevation and slope to guarantee slow, even ripening of fruit and frost protection. Accessibility to electric power is another consideration. If a winery is to be included with the vineyard, the site should reflect the need to locate in an area favorable for winery retail sales.

EQUIPMENT

The costs associated with equipment and machinery vary for different vineyard sizes and establishment practices. Vaden and Phillips (1982) estimated that a ten acre vineyard in Virginia would require $35,650 worth of machinery. Annual repairs were estimated at one to three percent of the purchase prices. White and Jordan (1978) estimated that the typical grape equipment fixed costs for a fifty acre vineyard in the Great Lakes Region would be $45,050. Smith (1981) estimated that the minimum

Figure 3. Active Management Areas and Irrigation Non-Expansion Areas in Arizona.



Source: Water Resources Department of Tucson Active Management Area. 371 South Meyer Ave. Tucson, Arizona.

cost of items of equipment required to run a vineyard to be $27,800. The costs were for new equipment. The major purchases for all the studies were tractors, pick-up trucks and spray rigs. These will also be the major equipment outlays for vineyards in Arizona.

A major item overlooked in most vineyard studies is the cost for an equipment service center. White and Jordan (1978) assumed one building with combined shop and machinery storage. In their model a building 48 by 36 feet was suggested with one end of the shop area, 16 by 36 feet, finished with a concrete floor. The estimated initial cost of the building was $8,100. The author suggests the following basic features common to farm shops adequate for servicing and minor repairs of big machinery; big doors, complete sets of hand tools, stationary power tools and portable power tools, a welder, parts storage, good lighting, compressed air, water and heat. Areas should be included for metal work, wood work, general repair, storage and service. A seperate room for storage and handling of spray materials is also recommended.

ESTABLISHMENT AND MAINTENANCE

High flucuation is exhibited in the costs of developing trellis systems for premium wine vineyards. Dutt (1980) found per acre costs, based on a forty acre planting with a 7' by 12' spacing, 522 vines per acre, to range from

$443.70 for a head-trained system on stakes, to $1196.94 for a Geneva double curtain using posts, deadmen and crossarms. Vineyards are known to remain viable forty to eighty years. High quality materials must be employed in trellis construction to ensure durability. In Arizona the author suggests the addition of a bottom wire and clamps to support the drip irrigation lines off the ground. Wire borne irrigation lines are exposed to less damage from pests and machinery, and contribute to cultivation efficiency by allowing for mechanical cultivation via a French plow or grape hoe.

Careful attention should be given in laying out a vineyard to prevailing winds and sun exposure. A novel concept that could be incorporated into a vineyard design is water harvesting. Coupal (1985) estimated construction and operating costs for an eight acre vineyard in the Page Ranch experimental water harvesting system. The water harvesting system consisted of a series of linear microcatchments with a four-foot strip at the bottom for growing crops. Water harvesting was the only source of irrigation water available for the crops grown in the system. A fifteen year cash flow summary for the vineyard operation was presented. The study concluded that land necessary to collect enough irrigation water in a water harvesting system for a vineyard was too large to be economically feasible. A more practical usage for water harvesting would be to combine it with drip

irrigation and use it as a means of conservation and a supplemetary water source. Contour planting coupled with a series of grape mounds and clean cultivation would be one method.

Vaden and Phillips (1982) found that establishment and production costs were influenced primarily by variety, vine spacing, training system, cultural practices and pest control. Savage and Hamman (1984) found that it was extremely difficult to project true costs of establishing and maintaining vineyards in cases of small acreage because of the various trade offs between labor costs and equipment costs. The costs of an irrigation system was found to vary widely from $500 an acre for gated pipe to $1500 an acre for an automated microsprinkler system which would reduce long term labor costs.

White and Jordan (1978) point out that the typical family farm vineyard and winery must also devote attention to non-cash costs such as owner management. Production decisions, labor management, purchasing decisions, marketing decisions, planning and coordinating as well as financing and record keeping are all aspects of winegrowing management that must be addressed. The value of owner management is difficult to isolate since the operator frequently performs the dual tasks of manager and laborer, often simultaneously. Procedures for estimating the value of management include a

flat annual fee, independent of farm size; a flat per acre fee; a percentage of gross receipts; a percentage of total expenses; a flat annual fee plus a percentage of net receipts; or a charge per unit of time worked.

Booze-Allen & Hamilton Inc. (1982) conducted a study of the commercial feasibility of grape and wine production on University of Texas lands. The primary purpose of the project was to explore the practicality of establishing a new agricultural industry on the University's West Texas landholdings that would increase the University's income from the land surface and hedge against the ultimate decline of oil and gas lease and royalty income. They found that the time frame for evaluation of the economic feasibility of a vineyard venture was longer than typically expected. Results that looked very unfavorable at the end of ten years became very favorable at the end of twenty years. The project was found to be feasible under certain conditions; a large scale size, focus on white wines, competitive prices, partnership with a strong marketing organization and a long-term commitment. The long-term nature of vineyard and winery investments must be appreciated at the outset if the project is to have a reasonable chance for success. The industry joke about the capital intensive nature of the business is; "the way to make a small fortune in the wine industry is to start with a large one".

Kirpes and Folwell (1984) estimated the costs of

establishing and maintaining a fifty acre wine grape vineyard. They analyzed the rates of return for specific wine grape varieties. The estimated profit level was found to vary by variety due to the differences in yields and prices. While the average estimated profit level for the vineyard given eight different varieties was $427.13 per acre, the most profitable variety, Chardonnay, produced $984.28 per acre, while the least profitable variety, Gerwuztraminer, lost $146.39 per acre. The realized rate of return (RRR) was determined for the fifty acre vineyard. RRR differed from the internal rate of return (IRR) in that IRR assumed that the net cash inflows were reinvested and earned interest at the IRR. The RRR assumed that the net cash inflows were reinvested in alternative investments where returns differed from that of the original investment. The investment was profitable if the RRR exceeded the cost of capital. The average RRR was determined for each variety by randomly selecting different yields and grape prices for a thirteen year production period, various discount rates were used to show the effects on the rates of return (TABLE 3).

The range in average RRR's was from 12.1% for Gewurztraminer with a 10% discount rate to a high of 15.5% for Chardonnay with a 14% discount rate in cases of 100% equity position or where it was assumed that the total initial investment amount for the establishment years was

TABLE 3
Summary of the Realized Rate of Return for Eight Wine Grape Varieties at Various Equity Positions, and Before-Tax Discount Rates.

Variety	100% Equity Position Before-tax Discount Rates 10%	12%	14%
	%	%	%
Cabernet Sauvignon	12.59	13.29	14.02
Chardonnay	14.27	14.88	15.50
Chenin Blanc	13.24	13.91	14.60
Gewurztraminer	12.05	12.81	13.61
Merlot	13.18	13.85	14.54
Sauvignon Blanc	13.94	14.57	15.21
Semillon	13.93	14.62	15.32
White Riesling	13.98	14.67	15.38

Variety	80% Equity Position Before-tax Discount Rates 10%	12%	14%
	%	%	%
Cabernet Sauvignon	15.23	16.05	16.89
Chardonnay	16.54	17.20	17.89
Chenin Blanc	15.64	16.39	17.16
Gewurztraminer	14.55	15.41	16.30
Merlot	15.57	16.32	17.08
Sauvignon Blanc	16.43	17.14	17.87
Semillon	16.20	16.95	17.73
White Riesling	16.25	17.00	17.78

not borrowed. In cases of less than 100% equity it was assumed that 80% of the monies for the vines and trellis materials was borrowed at 14% for 7 years. The less-than 100% equity position produced a higher realized rate of return than the 100% equity position due to the increased cash flows in the early production years. This increase was the result of a lower income tax burden.

There is an important lessons derived from the study for potential Arizona winegrowers. Varietal selection will have an influence on profitability. The profit level will vary by variety due to the differences in establishment costs, yields and prices in the vineyards, and vinification practices in the wineries (Table 4).

TABLE 4

Suggested aging cycles for premium wine varieties.

VARIETY	BARRELS	WOOD TANKS	BOTTLE AGE
Cabernet Sauvignon	2 Years	-	1 Year
Pinot Noir	18 Months	-	1 Year
Merlot	1 Year	-	1 Year
Zinfandel	-	1 Year	6 Months
Chardonnay	6 Months	-	6 Months
Fume Blanc	6 Months	-	6 Months
Sauvignon Blanc	-	-	3 Months
Chenin Blanc	-	-	3 Months
Riesling	-	-	3 Months
Gewurztraminer	-	-	3 Months
Semillon	-	-	3 Months

What the exact variation in profit will be in Arizona for each variety is an unanswered question. The same

holds for variation associated with financing a winegrowing operation. A degree of control may be exercised over equity position but not over the cost of capital or taxes. The equity margin, cost of capital and taxes are influences that will definitely impact on profitability.

WINERY STUDIES

Peterson (1975) provided an indepth look at the information and decisions which should be reviewed and completed prior to planning a winery. He described the fixed conditions that should be determined from the outset as, the business plan, the source of grapes, the source of capital, and the source of personnel. After the basic preconditions were met, the actual calculations for building and equipment size could begin (Appendix C). Robbins (1980) estimated $40 a square foot for constructing a winery building. For a 25,000 case capacity premium winery he projected operating costs of $35.25 a case and investment costs of $43.65 a case. Equipment costs would be $682,800 to set up a winery with standard presses, pumps, barrels, refrigeration equipment, bottling and labeling equipment and other materials. The estimation of costs were considered to be in the middle range for all items.

Cooke, Reed and Keith (1977) offered guidance to those factors in design that influenced costs in the construction of wineries, and presented examples of

approximate costs for building table wineries for wholesale, retail, and direct sale markets for several sized wineries in California. They estimated that construction of a winery involved nearly 24 governmental and related agencies including an enviromental impact report. They recommended having a master plan since all required facilities were rarely built in the first year. The master plan should include the number of construction phases, the starting date for each phase and the approximate cost of each phase. The factor of inflation should be considered in long-range cost projections. An analysis of the cost components listed in their table revealed that the cost for the building, processing equipment and contingencies which covered material testing, design, inspection and construction management, accounted for 78 percent to 89 percent of the total cost to build the representative wineries. It snould be noted that a considerable portion of the processing operations of wineries constructed in Arizona could be located outdoors, thus minimizing the need for building space and therefore reducing total construction costs.

Webb (1976) stated that the small winery must have approximately 250 gallons of fermenter capacity per ton of grapes to be fermented. The size of the small winery would vary significantly with the type and quality of the wine to be produced. White wines require little aging and a minimum of storage capacity, red wines require several years of

aging in small oak barrels and later in bottles. Consideration had to be given to federal, state and local regulations before building the winery. Winery building costs varied tremendously depending upon the amount of time and material invested in the aesthetics of the structure as compared with strict utility. The work estimated the cost for a well-constructed, vintage varietal style winery of about 25,000 gallons capacity, to be about $45 per gallon or slightly over one million dollars (Table 5).

Ledgerwood (1981) researched a cash flow cycle for a new winery with a 12,000 gallon capacity in New York. He assumed that a suitable tasting and sales facility was already available and that no advertising expenses were included in the budget. All costs were financed. The cumlative operating expenses became the major credit need and were the most difficult to finance. The article stressed the importance of a sound financial package prior to starting a winery. Recommendations were made to concentrate efforts on quality wines to ensure success in marketing.

Brady (1982) combined a ten acre vineyard with a 5,100 gallon capacity winery in Virginia to estimate cash flows. All ten acres were planted in the first year with the winery constructed in the third year. Half of each year's wine production was sold at retail and half at wholesale. Total debt was slowly retired over the course of time starting in

TABLE 5
Summary of Winery Construction Costs and Costs Per Gallon.

Author	Year	Gallons	Cost	Per Gallon
Robbins	1980	60,000	$1,774,050	$29.50
Cooke	1977	24,000	$793,000	$33.00
Cooke	1977	240,000	$3,620,000	$15.00
Webb	1976	25,000	$1,125,000	$45.00
Ledgerwood	1981	12,000	$159,660	$13.30
Brady	1982	5,100	$102,000	$20.00
Key	1982	12,000	$157,223	$13.10
Castaldi	1984	10,000	$269,330	$25.93
Castaldi	1984	30,000	$523,472	$17.45
Castaldi	1984	100,000	$1,572,050	$15.72

the fourth year. In the twelfth year a positive cash flow occured, this was nine years after the first wine was released. Key (1982) presented economic analysis for a New York vineyard investment and a small-scale winery. He shared Legerwood's assumptions. The analysis used the net present value method of evaluating investment proposals. The study examined a fifty acre vineyard and a 12,000 gallon capacity winery. Investment in either a winery or a vineyard were found to be worthwhile on an after-tax basis if wine grape prices kept up with inflation. If one invested in both projects, considerable income would accrue to the owner over the long run, however capital costs would be twice as high in a joint operation as in a vineyard investment without the supporting winery. Grape prices and inflation were shown to have a very large impact on the profitability of the enterprise. In times of accelerating inflation rates, the degree of risk being assumed also accelerated since costs and incomes become increasingly difficult to project with confidence.

Castaldi (1984) examined the economic feasibility of potential investments in small premium wineries in Washington State. The objectives of the study were to determine the total investment cost in terms of land, buildings, and equipment for five different sized wineries, given various assumptions regarding production costs, product mix and product prices. Attempts were made to define

and calculate the cost of producing a bottle of wine. Estimates of cash flow data were then analyzed to determine the overall feasibility and attractiveness of each size winery as an investment opportunity. Despite the relatively high initial investment cost and negative cash flows which occurred during the early stages of operation, the study found that winemaking could be a very profitable investment capable of generating a desirable rate of return. Initial investment costs for equipment, land and buildings for a small winery were over a quarter of a million dollars.

Coupal and Angus (1985) conducted sensitivity analysis for a twenty acre vineyard and a 3,600 gallon winery budget in Arizona. The cost of land was excluded from the budget. The net present value of returns over a 15 year period were examined assuming no inflation. They found that the factor that had the greatest impact upon the net present value was the discount rate. A one percent change in the discount rate could elicit a change in the net present value from $8,600 to $32,400. For a one percent change in output, holding all inputs constant, the change in net present value varied from $2,100 to $3,400. The net returns for the winery were estimated assuming it was financed with 50 percent borrowed funds at 12 percent. A mixture of 10 percent premium wine and 90 percent generic wine was also assumed. The sensitivity analysis showed that tax rates could have a

significant impact upon the net present value of a winery investment. A one percent change in the corporate tax rate would cause a $9900 change in the net present values. Marketing effects were also evaluated by adjusting the proportion of premium and generic wines sold. At a 30 percent tax rate, a one percent increase in the proportion of premium wine sold would result in a $29,977 change in net present value.

Gorenz, Strano and Wolfe (1984) developed a generalized vineyard and winery model for an Arizona winegrowing venture as an alternative to cotton growing. No attempt was made to estimate specific costs. The current composition of assets, liabilities and sales of each industry were measured against each other. The solvency ratios, quick ratios and the current ratios for both grapes and cotton were very similar. According to the authors, cotton was found to have a less secure position for creditors than the grape industry. The current liabilities to net worth ratios indicated a less secure position for grapes than cotton. The return on assets for grapes was found to be more than twice as much as for cotton.

MARKET STUDIES

Clark Gavin Associates Inc. (1984) predicted that in promoting table wines, wine marketers would have to keep in mind the fact that they would be competing not only against

malt-beverages and the various types of distilled spirits, but against all the many other types of beverages consumed with meals (TABLE 6). The most important U.S. wine trend was viewed as being the ascendancy of table wines. The report stated that large numbers of Americans had become accustomed to having wine with meals on a fairly regular basis. It was in the furtherance of this frequency rate that marketers should place their hopes for the future.

Folwell and Baritelle (1977) investigated the market structure and the various segments served by the U.S. wine industry. A panel consisting of approximately 7,000 households was used. Data showed that households purchasing table wine, varietal and nonvarietal, had significantly more education and higher household incomes. The demographics of table wine purchasing households did not differ significantly betweens regions. In contrast, the households that bought sweet wines and flavored wines tended to be slightly less educated with smaller household incomes and bigger families. The demographic structure of sparkling wine purchasing households tended to be like the table wine purchasing households. While there was some degree of brand preference for all wine types, the panel of households did not show strong brand preference for all wines produced by a single company.

Total Research Corporation (1981) conducted a study to determine preferred beverages, whether alcoholic or

TABLE 6
Consumption Trends by Beverage 1979-1983 (millions of gallons).

Beverage	1979	1980	1981	1982	1983	trend '79-'83
Soft Drinks	8,246	8,588	8,909	9,149	9,617	3.9%
Coffee	6,558	6,080	6,128	6,050	6,060	-2.0%
Beer	5,341	5,512	5,650	5,653	5,672	1.5%
Milk	4,715	4,703	4,682	4,636	4,633	-0.4%
Juices	1,505	1,565	1,535	1,530	1,590	1.4%
Powdered Drinks	1,345	1,360	1,375	1,390	1,520	3.1%

Source: Jobson Publishing Co. (1985).

non-alcoholic, for upscale income, adult consumers, aged 21 to 54, in 17 different situations ranging chronologically from luncheon to after-dinner to before retiring. The work also examined changes in beverage preferences and the relationship between demographic and lifestyle characteristics and beverage preferences, as well as changes in preferences. Wine was found to be consumed in each of the 17 situations studied; particularly at home with friends or with business guests for dinner. Beverage preferences appeared to have been relatively stable over the three years surveyed, with only 15 percent of consumers changing either alcoholic or non-alcoholic beverage preferences. Wine accounted for 30 percent of those changes recorded. The reasons given by consumers for changing to wine reflected growing consumer consciousness about health and diet. Peer influence and increased popularity of wine were also important factors shifting consumer preferences.

Folwell and Baritelle (1978) found that half of U.S. households never bought wine and less than 5 percent purchase more than half the wine consumed in the United States. The two important variables that influenced the amount of wine purchased were wine price and income level. Households that bought the most wine paid lower average prices, gaining economies of size in their buying. The four largest wine companies accounted for 54 percent of all wine sales. The average prices paid per ounce for the various

wine types produced by the largest companies in the United States differed among regions partly due to varying taxes imposed by the states

Cannon (1983) predicted that wine consumption would continue to expand in the United States at an average annual growth rate of 6 percent. Americans would choose to drink more wine as the economy improved, as the population in the 25 to 45 year-age group increased, as states relaxed their regulations of alcohol sales and as industry marketing campaigns persuaded consumers to drink more wine. Marketing was viewed as the key to persuading consumers to increase their consumption of wine. Despite overall growth in wine consumption, sales would be affected by fluctuations in economic cycles.

CHAPTER THREE

ANALYTICAL MODELS AND REPRESENTATIVE BUDGETS

Agricultural economic analysis frequently assumes that farmers operate as if profit maximization were their single goal. In fact no single objective can express all of the complexities incorporated into financial management. Sample alternative goals could be: to attain a target market share, stabilize prices or profit margins, avoidance of losses, increase leisure time, or provide community service (Boehlje and Eidman 1984). While recognizing that potential winegrowers may frequently have other objectives, including some which may conflict with profit maximization, the assumption is made here that the primary objective of the wine business is to maximize the economic well-being of the owners.

Small, premium vineyard and winery ventures require large capital expenditures which are permanent in nature and will influence the long-run earning power of the enterprise. The economic effects of capital investments in winegrowing occur over a considerable period of time in the future. Most of the capital must be expended in the first years of the project while the benefits accrue to the winegrower over many later years. The timing of outlays and

receipts is the crucial component of the capital budgeting process.

From the standpoint of investment analysis, "time is money". A dollar received next year is not equivalent to a dollar held today. This stems from the investment possibilities for today's dollar. Today's dollar can grow over time. Interest rates serve as the pricing mechanism for the time value of money (Levy and Sarnat 1986). A dollar in hand today is certain, there is risk associated with any alternative investment, which could result in depreciation of assets. Inflation can also serve as a mechanism to lessen the value of future monetary holdings.

NET PRESENT VALUE

The purpose of agricultural economic profitability analysis in winegrowing is to determine whether the enterprise will contribute to the long-run profits of the winegrower. The net present value (NPV) is a capital budgeting concept for evaluating the desirability of investments. NPV employs a discounting formula for a payment series to value the projected cash flows for each investment at one point in time. NPV directly accounts for the timing and magnitude of outlays and receipts. An investment's NPV is derived by discounting the net cash receipts at a rate which reflects the return which a firm can earn on its capital in the financial market or the

minimum required return for the firm. The discounted cash receipts are summed over the life of the investment and then the initial investment outlay is subtracted. Reliable cash flow projections are required for accurate evaluation. NPV can be set up as follows:

$$NPV = S/(1+K) + S/(1+K)^2 + S/(1+K)^3 \ldots + S/(1+K)^N + V/(1+K)^N - I$$

where:

S = the net cash receipt at the end of each successive year,

K = the discount rate, i.e. the required minimum rate of return on new investments,

N = the length of the project's planning horizon,

V = any salvage or terminal investment value,

I = the present value of the investment outlays.

The sign and size of an investment's net present value determine its ranking and desirability. The decision rule for winegrowers seeking to maximize profits would be to accept the project if the NPV were positive and reject it if the NPV were negative. The present value of net cash inflows when discounted with the minimum acceptable rate of return, represents the maximum amount that the winegrower could afford to pay for the benefits expected and just

"break even" (Casler, Anderson and Aplin 1984). An investment with a positive net present value will yield a return greater than the rate of return used as the standard in testing the proposal (K). A negative net present value would require investment outlays that exceed the maximum amount the winegrower could afford to pay without being financially worse off.

The discount rate is of crucial concern in NPV analysis since it indicates the minimum acceptable rate of return for an investment. Typically the rate employed in capital budgeting is the firm's required rate of return on its equity capital, referred to as its opportunity cost. The opportunity cost of capital for a particular investment is the rate such equity capital could earn in its most favorable alternative use.

INTERNAL RATE OF RETURN

Another time discount measure of investment worth is the internal rate of return (IRR). The IRR is the discount rate that equates the present value of the expected future cash flows, or receipts, to the initial cost of the winegrowing venture (Brigham 1979). The IRR can be compared to alternative rates on other investments to determine if the particular investment is desirable. If the IRR exceeds the rates on other investments or the cost of capital, the project is acceptable; if not the project is

rejected. IRR is set up as follows:

$$I = S/(1+R) + S/(1+R)^2 + S/(1+R)^3 \ldots S/(1+R)^N + V/(1+R)^N$$

where:

I = the present value of the investment outlays,
S = the net cash receipt at the end of each successive year,
R = the internal rate of return,
N = the length of the project's planning horizon,
V = any salvage or terminal investment value.

In effect the IRR is the discount rate which equates the NPV of the winegrowing project's cash flow to zero. The NPV and IRR criteria, used in evaluating the profitability of alternative capital investments, will generate the same results in most winegrowing cases since they use similar data and computation procedures. Although both criteria give equivalent results, they do not rank projects the same. NPV reflects the absolute magnitude of the winegrowing projects while IRR does not. NPV implicitly assumes reinvestment of the interim cash inflows at the cost of capital, while IRR assumes reinvestment at the project's own rate of return. NPV provides an optimal solution to capital budgeting problems on the twin assumptions that the future cash flows are known, as well as the appropriate discount rate.

ENTERPRISE BUDGETS

An enterprise budget is a projection of average annual costs and returns for a proposed project. The enterprise budget is a practical method of summarizing cash flow projections for use in winegrowing management decisions. These decisions vary from analyzing trellis systems, to developing a leasing arrangement, choosing the time to replace equipment, or selecting the winery plan. The enterprise budget is based on the system of production that identifies the specific outputs to be produced such as grapes or wine, the sequence of operations, the approximate time the operations are to be performed, and the inputs required for the production process (Boehlje and Eidman 1983).

The data summarized with enterprise budgets are used with the capital budgeting procedures to complete financial analysis (Chapter 5). The enterprise budget includes an estimate of the physical resources required for production and products produced, their prices, and the total value of each resource and product per unit of the enterprise, projected over time. Enterprise budgets typically include a title describing the enterprise and any unique characteristics, cash inflows from output sales, the operating costs listed by item, the ownership costs also listed by item, and the returns per unit of production

above cash outflows. The data on enterprise costs and returns form the basis for vineyard and winery planning.

The figures developed for the representative budgets in this study are based on the costs associated with premium level vineyards and wineries. High quality materials, equipment and labor are employed to insure that the resulting grapes and wine are of the highest possible standards. The vineyards and wineries are expected to produce over forty years. It is with that planning horizon in mind that every effort is made to construct the enterprises with durable inputs. Prospective winegrowers in Arizona will be able to substitute lesser quality inputs for those delineated in this study for short-term gains, it is expected that the trade-offs would be apparent over time.

VINEYARD BUDGETS

Receipts

Three vineyard enterprise budgets, one each for a twenty acre vineyard, a fifty acre vineyard and a hundred acre vineyard are developed to reflect annual costs and returns in Tables 7, 8, and 9. Only Vitis Vinifera, the European grape varieties, are included in each model. Two-thirds of the vines planted are assumed to be white varieties such as Chardonnay, Sauvignon Blanc and Semillon, and one-third of the vines are red cultivars such as Pinot

Years Two Through Ten Shown Above.

Noir, Merlot and Cabernet Sauvignon. Expected vineyard production is as follows: (Table 10)

TABLE 10
Grapes harvested in tons.

YEAR	1	2	3	4	5	6	7.....20
PER ACRE	0	0	.5	1	2	3	4.....4
20 ACRES	0	0	10	20	40	60	80.....80
50 ACRES	0	0	25	50	100	150	200....200
100 ACRES	0	0	50	100	200	300	400....400

An average of four tons per acre is the expected maximum yield. Vineyard practices for wine grapes are aimed at restricting yields to improve quality in terms of sugar and acid ratios and pH balance. The expected market price for the enterprise budgets is $800 a ton, received at harvest.

Operating Costs

The variable or operating inputs for a vineyard include, land preparation, trellis and irrigation installation, planting and vineyard maintenance. Land is assumed to be cleared. Two foot strips will be deep plowed where the vines are to be planted to promote root penetration. The strips will then be disked and herbicide applied to begin weed control.

The trellis consists of a top wire supported by posts which will bear the vines and a bottom wire to secure

the irrigation lines off the ground. The trellis and irrigation drip system is installed prior to planting to insure water for the young cuttings. Rows are ten feet apart and six hundred feet long to promote efficiency for tractors moving along the rows of vines. Fifteen feet is left at the end of each row for turning space. Five hundred and twenty-five vines are planted per acre. The vines are spaced seven feet apart, one to a post in an T-shaped, double arm, high cordon, training method. The high cordon method is thought by the author to offer some reduction in heat summation from ground radiation, thus slowing ripening.

A grape mound under the trellis maintained by a French plow or grape hoe, will be the primary method of weed control. Hand cultivation around each vine will augment the system to keep wetted areas weed free. The thinning of buds and clusters, coupled with winter pruning is aimed at promoting even ripening and high quality fruit. Most of the costs during harvest are for picking labor. A seasonal distribution of inputs after vineyard establishment is illustrated by Table 11. Interest is calculated at 10% on 50% of the operating costs.

Drip irrigation is the system of water distribution assumed for this study. This method of irrigation uses plastic tubing and emitters to deliver the water to the

Source: Author's estimation.

root zone of each vine. The timing of applications and amount of water delivered will depend on the growth cycle, soil type, climate and rooting depth. The cost of pumping water is the primary input cost for irrigation once the well and delivery system has been installed.

Ownership Costs

Ownership or fixed costs are those cash outflows in vineyard production that will continue even if the enterprise were to halt. A list of machinery and equipment with prices is provided in Table 12. Irrigation and trellis costs are for materials used in construction. Table 13 gives a breakdown of these fixed costs. The drip system is depreciated in a straight line with no terminal salvage value at the end ten years, the trellis is depreciated over twenty years, as is the shop, well and cuttings. Machinery and equipment is depreciated over seven years with a ten percent trade in value at the end of the period.

Rooted cuttings are one year old, non-grafted, certified virus free vines. Land costs reflect prices in the Sonoita Viticultural District. For each vineyard, excessive land is purchased to allow for a well, turning space at the end of each row, buildings, a possible winery site, and parking. Twenty-five acres are allocated for the twenty acre enterprise, sixty acres are required by the fifty acre vineyard and one hundred and twenty acres for

SOURCE: Partially compiled from Angus and Luben (1984).

the one hundred acre budget.

Returns Above Costs Shown

Returns above costs shown are calculated by totaling vineyard operating costs and ownership costs, and then subtracting the total costs from gross receipts. No charges are reflected for management and overhead business expenses such as office expenses, transportation and utilities. Returns above costs shown represent a residual return to all factors for which a charge has not been shown. It is a return to the winegrower's management and overhead expenses of the vineyard (Boehlje and Eidman 1984). Vineyard financial analysis will be based on the enterprise cash outflows and receipts on an after tax basis.

WINERY BUDGETS

Receipts

Three winery enterprise budgets are presented in Tables 14, 15, and 16. The twelve thousand gallon winery can process the grapes from a twenty acre vineyard. The thirty thousand gallon winery is the necessary capacity for a fifty acre vineyard, and the sixty thousand gallon winery is sufficient to handle the crush from a one hundred acre vineyard.

All wines are assumed to be of premium quality. The

Years Three Through Ten Shown Above.

product mix is one-third red wines and two-thirds white ines. It is assumed that the twelve thousand gallon winery sells 30% of its wines on the premise at its bonded retail outlet, the balance is sold at wholesale prices off premise. The thirty thousand gallon winery sells 20% retail and 80% wholesale. The sixty thousand gallon capacity winery has a 15% to 85% ratio or retail and wholesale receipts.

One half of the white wines are sold in the second year after each harvest and the other half is sold in the third year. This reflects the wood and bottle aging process, and lags in inventory turnover. Red wines are sold in the fourth and fifth years after each harvest, with one half sold in each time frame. Premium red wines require extended wood aging and bottle aging. Table 17 shows the annual availability of wines for sale.

Operating Costs

The variable inputs for a premium, small winery are the grapes, packaging, marketing, labor, utilities, supplies, maintenance and interest on operating capital. The grapes are Vitis vinifera, similar to those grown in the vineyard budgets. The price for wine grapes is $800 a ton. Packaging costs refer to outlays for bottles, corks, labels and capsules. Quality materials are employed to enhance marketing of the wines. Marketing costs represent

0.087% of the average per case wholesale price. Castaldi (1984) found that the typical winery costs for marketing ranged from 3.75% to 9.50% of the wholesale price.

The service of a trained enologist is assumed for each winery budget, with part-time assistance employed at appropriate times of the season, such as during harvest and crushing, racking, bottling, and for tastings and sales. A seasonal work schedule for a winery is presented in Table 18.

Ownership Costs

Fixed costs for premium wineries include equipment, capital improvements, land, interest, insurance and taxes. A list of equipment and costs for each sized winery is provided in Table 19. Oak barrels are from American oak and are depreciated over five years which is their useful life. Stainless steel tanks used for fermentation and aging are depreciated over twenty years. Production equipment is depreciated over seven years. All the equipment is assumed to have a 10% terminal salvage value, straight line depreciation is used.

Capital improvements are listed in Table 20. Capital improvements are depreciated using the straight line method over twenty years with a 10% salvage value. Five acres are purchased for the twelve thousand and thirty thousand gallon wineries and seven acres are required for

the sixty thousand gallon winery. Land prices for the Sonoita viticultural district are utilized. The land is for the winery, out buildings, parking, landscaping and waste water treatment.

Returns Above Costs Shown

Returns above costs shown are obtained by subtracting total winery costs from total receipts. As in the case of the vineyard enterprise budgets, no charges are shown in the winery budgets for management and overhead business expenses. Winery financial analysis will incorporate these charges along with the enterprise costs and receipts. (Chapter 5)

CHAPTER FOUR

THE MARKET

The long-term growth of the American wine industry has been slow, with the per capita consumption rate increasing only .038 gallons on average per year between 1934 and 1984. Per capita wine consumption in the U.S. increased from .26 in 1934 to 2.29 in 1984 (TABLE 21).

In recent years the rate of wine consumption has accelerated over the historical norm. The wine boom years of 1968 to 1972 witnessed annual growth rates in excess of 10 percent. Consumption levels were forecasted on a per capita basis for the years 1900 and 2000 by Folwell and Kirpes (1982). Under the optimistic income scenario they presented, the projected consumption levels were 3.31 and 4.43 gallons respectively. Per capita consumption of all wine increased 1.19 gallons between 1980 and 1990 and 1.12 gallons between 1990 and 2000. The 1980s market growth rate was forecasted to be above that of the 1970s and slowing in its rate of increase in the 1900s.

In terms of average annual growth rates, the 1980s were expected to produce a 6 percent annual increase in all wine consumption, while the 1990s were expected to slow to 3.6 percent per year. The projected total consumption of

U.S. produced table wine was 747.5 and 1,126,7 million gallons for 1990 and 2000. These projected consumption levels represent a higher proportion of table wine to all other wines than exhibited in the past. The changing product mix was attributed to increasing preference in the market for table wines and the expected higher national income levels. Booze-Allen & Hamilton (1982) predicted total consumption in 1990 to hit just below 1,100 million gallons (Figure 4).

The United States ranked sixth among the wine producing countries of the world in 1985. France, Italy, the Soviet Union, Argentina and Spain had greater aggregate production (Table 22).

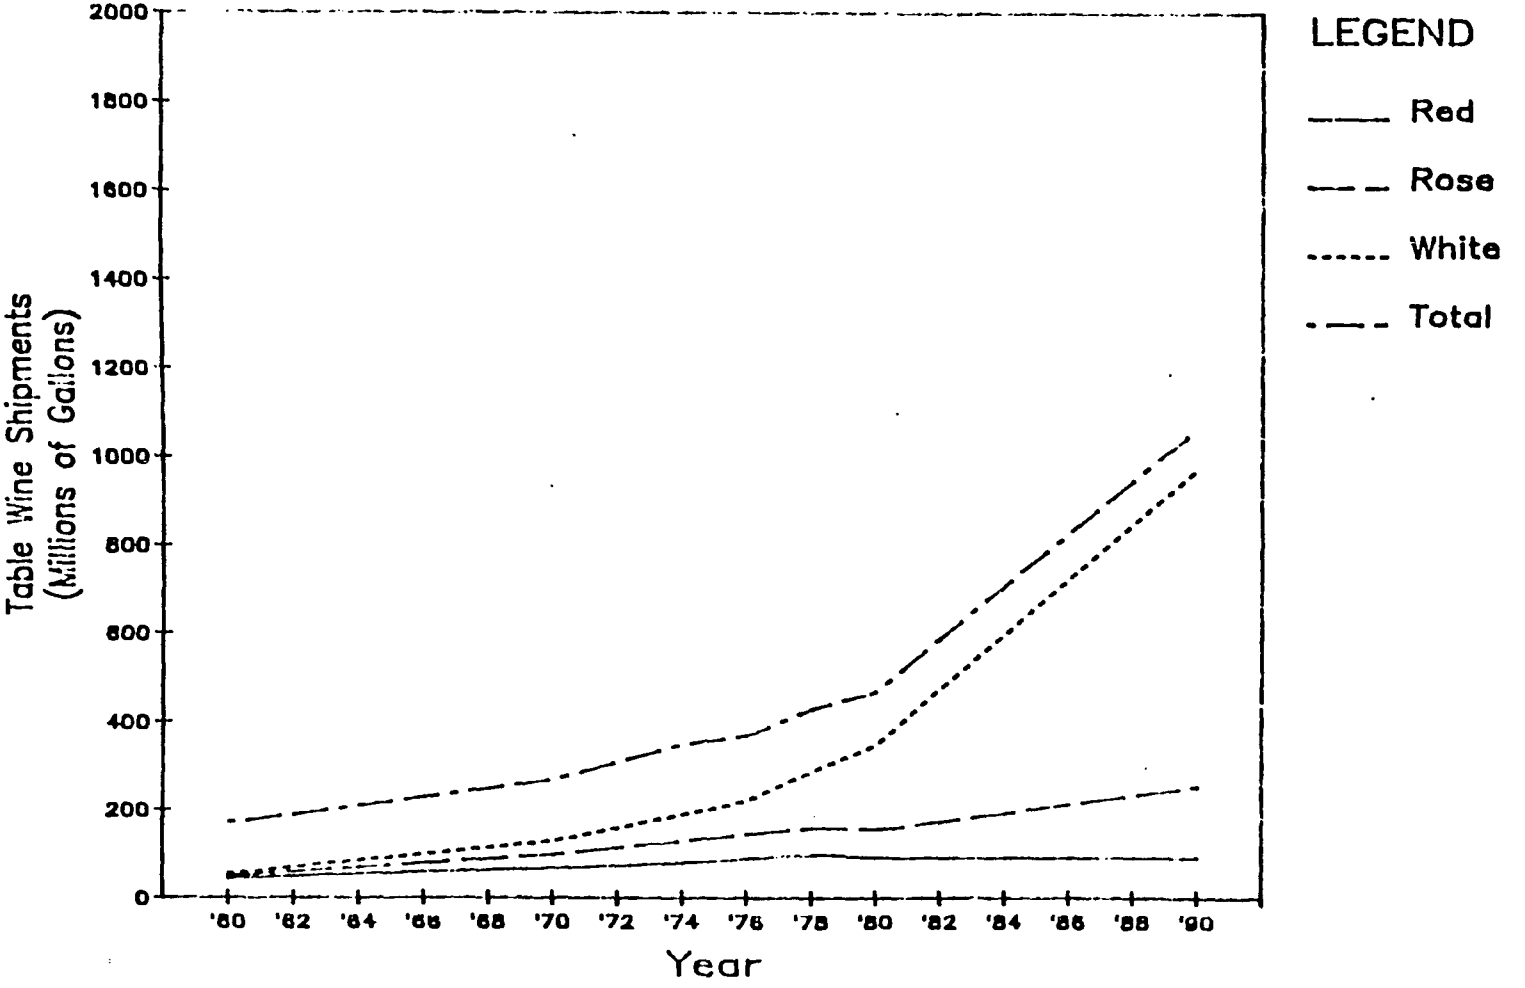
Per capita wine consumption in the United States was significantly below that of other major wine producing countries of the world. The per capita consumption of these countries ranged from 3.43 gallons in the Soviet Union to

Figure 4. Forecast Growth of the U.S. Wine Market, 1980 to 1990.



Source: Booz-Allen & Hamilton (1982)

21.66 gallons in France (Table 23).

Table wine, which is defined as unflavored, still wine, not over 14 percent alcohol, accounted for 65.4 percent of the U.S. wine market, compared to only 53.3 percent in 1973, but down from the 76.4 percent figure set in 1983. The decline in market share from 1983 to 1985 was due to the dramatic increase in wine cooler sales.

Wine coolers are a blend of light wines with carbonated citrus juices. Jobson Publishing Corp. (1985) estimated that there was a 5.9 percent increase in sales for all wines including wine coolers in 1984 in the United States. Total wine sales without coolers were up 1.4 percent. Coolers recorded sales of 12.1 million cases in 1984 which represented a 253.7 percent increase from the previous year (Table 24). In 1984 consumer expenditures for wine amounted to $8.3 billion. Dollar sales for all wines, unadjusted for inflation, were found to have more than doubled since 1977.

In 1984 wine consumption accounted for 2.5 percent of the American consumer's total beverage intake. In the per capita consumption trends by beverage, wine ranked above only distilled spirits. Since 1969, soft drinks have doubled their per capita consumption, coffee and milk have declined and distilled spirits have remained about even. Beer, juices, bottled water and wines have advanced (Table 25). While the various beverages are not perfect substitutes,

wine competes for market share with both alcoholic and non-alcoholic beverages.

Wines and Vines Magazine, (July 1986), reported that sales of all major traditional wine catagories were down in 1985, but that the 152.1 percent increase in wine cooler sales, fueled a 4.1 percent increase in total U.S. wine consumption. Wine shipments, including wine coolers, were up 6.9 percent to 440.5 million gallons. For the decade ending in 1985, total wine sales grew at an average annual rate of 4.6 percent (Figures Five A, B, C, and D). Wines and Vines (Sept 1986) reported that for the first six months of 1986, wine shipments from Calfornia were up 11.4 percent.

Arizona Consumption

Arizona consumed 3,022.6 thousand cases of wine in 1984 (7,254,240 gallons) up from 2,845.7 thousand cases (6,829,680 gallons) in 1983 and 1,330.0 thousand cases (3,192,000 gallons) in 1974 according to Jobson Publishing Corp (1985). Phoenix ranked 16th in the top metropolitan areas for total wine consumption in the U.S. and Tucson ranked 47th. Phoenix ranked 22nd in the 50 largest metropolitan areas by population and Tucson was not ranked. Wine consumption per adult in Arizona in 1984 was 3.82 gallons, up from 3.74 gallons in 1983. Arizona ranked 15th in the country in adult per capita consumption. In consumption per $1 million of income Arizona ranked 9th. In

1985, Wines and Vines Magazine also showed Arizona 15th in per capita wine consumption with a 5.6% increase from 1984 (TABLE 26). Total wine consumption in Arizona in 1985 was 8,983,000 gallons. It is the author's estimation that Arizona produced roughly .002% of the wine it consumed in 1985, in state bonded wineries. In 1986 Arizona produced approximately .003% of the wine it consumed for that year.

The per capita wine consumption in Arizona has increased from 1.06 gallons in 1950 to 2.82 gallons in 1985. The average growth rate during this period has been 3%. From 1970 to 1980 the growth rate was 4.7%, and since 1980 it has been 5.5%. Changing per capita consumption levels accounted for 62% of the growth in wine consumption and 38% of the change was attributed to population advances. The partitioning of the growth on a per capita versus population basis was calculated by multiplying the 1950 per capita consumption level by the 1985 population level. That amount was then subtracted from the total consumption for 1985. The difference was attributed to the increase in the per capita consumption.

The projected consumption level for the years 2000 and 2015 were obtained from a per capita income - per capita consumption function relationship and forecasted income and population levels. The first phase consisted of setting up the consumption function. Income has been identified as the primary variable responsible for changes in the demand for

wine (Folwell and Kirpes 1985, Wohlgenant 1985). Wine prices, prices of competing beverages and per capita education levels are not available for Arizona on an annual basis and are not included in this estimation. A simple regression model was set up with the wine consumption function expressed as follows,

$$C_t = a_t + b_t x_t + m_t$$

where C_t = the Arizona per capita consumption level of wine, X_t = the Arizona per capita income level deflated by the Consumer Price Index, a_t, b_t = the independent coefficients and m_t = the stochastic error term. The subscript t denotes the respective year.

Ordinary least squares was employed to estimate the parameters since this technique is known under the Gauss-Markov theorem to give the best linear unbiased estimators available (Salvatore 1982). The explanatory variable was pre-determined. Annual data sets for per capita income and per capita wine consumption in Arizona were used from 1950 to 1985. The year 1967 was the base year for personal income deflation (U.S Department of Commerce, 1985).

The results of the regression indicated a positive correlation between income and wine consumption. The adjusted R-squared was .966 (Table 27). The Hildreth-Lu Technique was employed in the regression to reduce problems associated with serial correlation. The resulting Durbin-Watson statistic is 2.27112. The independent coefficient was

0.000508, with a significance level of .003.

An ex post forecast was run to validate the forecast model. In an ex post forecast the forecast period is such that observations of both the dependent and independent variables are known with certainty. In this case the data for Arizona per capita income and per capita wine consumption was used from 1950 to 1984 to predict the level of consumption for 1985. The 1985 per capita consumption is known. The ex post forecast can be checked against the 1985 data to provide a means of evaluating the forecasting model (Pindyck and Rubinfeld, 1981).

The 1985 per capita consumption for Arizona was 2.82 gallons. The ex post forecast yielded an interval of 1.83 gallons to 2.29 gallons. This check indicates that projections based on this model will tend to error on the conservative side. Given the uncertainty and variability in long term forecasts, the preferred tendency would be to under estimate future consumption levels.

Future Wine Consumption

The second phase of the anaylsis was to extend the forecasted per capita consumption to the years 2000 and 2015. The estimated value of X_f , the total per capita income of Arizonans in the year 2000 deflated by the base year is $6,891 (BEA Regional Projections 1985). The new model takes the form,

$$C_f = a_f + b_f X_f + m_f$$

where C_f is the future value of C corresponding to X_f ,and m_f is the value of the disturbance term in this future period (Kelejian and Oates 1981).

The estimated forecast error variance is:

$$SF^2 = S^2 (1 + 1/N + (X_{t+1}-XBAR)^2 / SUM(X_t-XBAR)^2$$

The resulting value of SF^2 = .024. The 95 percent confidence interval is;

Y estimate $_{t+1}$ - t .05 SF less than or equal to Y_{t+1} less than or equal to Y estimate $_{t+1}$ + t .05 SF.

C_f = 3.50 plus or minus .31 for the year 2000 and

C_f = 4.04 plus or minus .36 for the year 2015.

The estimated population for Arizona in the year 2000 is 4,882,900 (Arizona Dept. of Economic Security). The range for per capita wine consumption is 3.81 gallons under optimistic conditions and 3.19 gallons under pessimistic conditions. Under the optimistic scenario total wine consumption would reach 18,603,849 gallons. This represents an increase of 962,0842 gallons over 1985 levels or a 107% increase in the 15 year interval. Under the pessimistic scenario, wine consumption will increase to 15,576,451 gallons which is an increase of 6,593,451 gallons or 73% (Table 28).

The estimated population of Arizona in 2015 is 6,740,000. The estimated value of X_f the total per capita income of Arizonans in the year 2015, deflated by the 1967

TABLE 28

FORECASTED ARIZONA WINE CONSUMPTION

YEAR	POPULATION	PER CAPITA CONSUMPTION	GALLONS
1985	3,197,700	2.82	8,983,000
2000	4,882,900		
Optimistic		3.81	18,603,849
Pessimistic		3.19	15,576,451
2015	6,740,000		
Optimistic		4.41	29,723,400
Pessimistic		3.69	24,870,600

SOURCES: Arizona Population Projections 1986, and BEA Regional Projections 1985.

base year is $7,978. The range for per capita consumption is 4.41 under ideal circumstances and 3.69 in the more conservative projections. Optimistic results yield total consumption of 29,723,400 gallons of wine in Arizona in 2015. This represents an increase of 11,119,551 gallons over the year 2000, and an increase of 20,740,400 gallons over consumption in 1985. The less favorable model shows consumption in the year 2015 to be 24,870,600 gallons. This figure is 9,294,149 gallons above consumption in the year 2000 and 15,887,600 gallons more than consumption in 1985.

Projected Vineyard and Winery Demand

A 10% market share of Arizona's own wine consumption, for native wines, is a target percentage being focused upon by the Arizona Wine Growers Association (Brady 1986). A model using forecasted consumption levels, with the assumption that 5% of the market is captured by the year 2000 and 10% by the year 2015 is used to determine the derived demand for vineyards and wineries necessary to be physically able to capture the stated market shares.

Vineyards are assumed to produce four tons per acre and one-hundred and fifty gallons of wine per ton. Wineries are assumed to have 25,000 gallon capacities. To achieve any level of market share it must be recognized that there is a seven year lag between planting a vineyard and full maturity. There is also a lag associated with aging wine and capturing market share.

Under optimistic conditions in the year 2000, Arizona would have to produce and sell 930,192 gallons of wine to attain a 5% market penetration. This would require 6,201 tons of fruit or 1,550 acres of vineyards. Vinification of the fruit would employ 37 bonded wineries (Table 29). The figures for the pessimistic conditions would be 778,822 gallons of wine, 5,192 tons of premium grapes, 1,298 acres of vineyards and 31 farm wineries in Arizona.

In the year 2015, if a 10% share of the indigenous market were to be gained, 2,972,340 gallons of table wine would be fermented by 118 small wineries. The crush would consist of 19,815 tons of grapes from 4,954 cultivated acres. Under less favorable conditions, 100 wineries would process 2,487,060 gallons of wine from 16,580 tons of fruit off of 4,145 acres of vineyards.

The model is not meant to predict the actual mix of vineyards and wineries but to demonstrate the potential scope of the Arizona wine industry under very modest growth projections. In the year 2015 if Arizona reached a 10% market goal, 90% of its own consumption would be imported from out of state. Following the same assumptions for instate vineyards and wineries, under conservative conditions, 22,383,540 gallons of wine would be imported from out-of-state. This figure represents 149,223 tons of fruit or 37,305 acres of grapes and 895 small wineries of

TABLE 29
Projected Vineyard and Winery Demand

Year	% Total Consumption	Gallons	Tons	Vineyard Acres	Wineries
2000	5%				
Optimistic		930,192	6,201	1,550	37
Pessimistic		778,822	5,192	1,298	31
2015	10%				
Optimistic		2,972,340	19,815	4,954	118
Pessimistic		2,487,060	16,580	4,145	100

25,000 gallons capacity.

There is precedence for such growth. In 1970 in the Napa Valley of California there were approximately 30 wineries, in 1985 there were approximately 150 wineries. In Virginia in 1970 the were no bonded farm wineries, in 1985 there were 32. Between 1980 and 1985, 467 new bonded wineries opened in the United States with approximately half of them located outside of California (Table 1, Chapter One).

Marketing

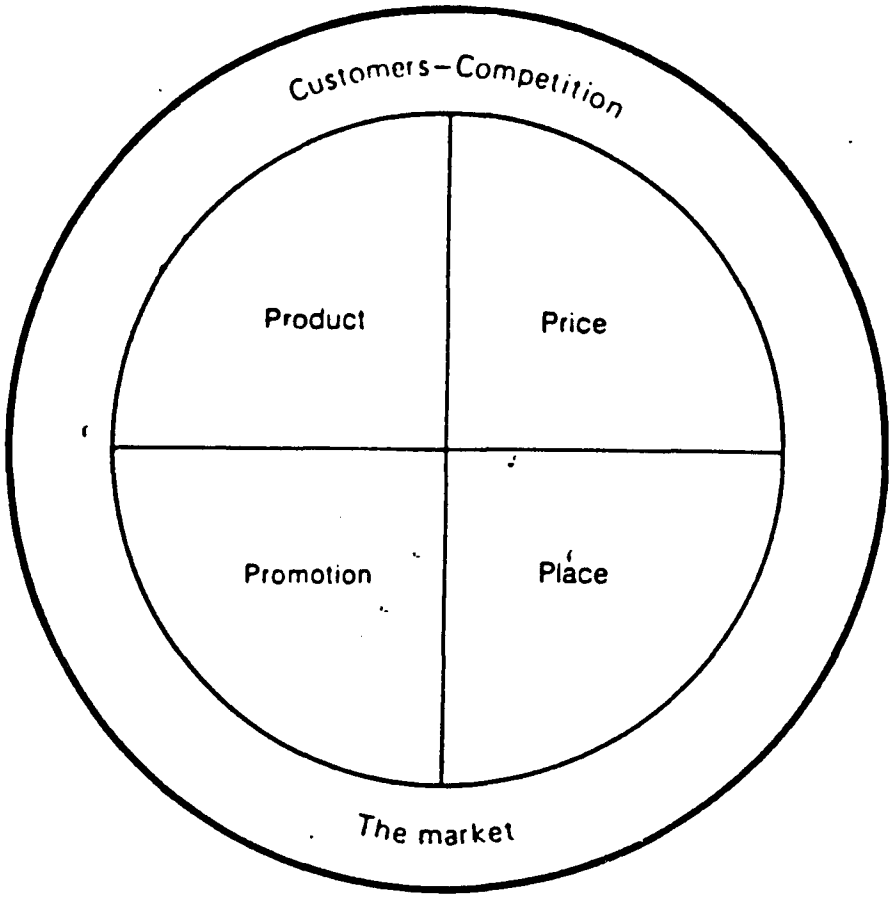
Cannon (1983) claimed; "Marketing will be the key to persuading consumers to increase their consumption of wine." Cimino and Filice (1984) defined marketing as: "a combination of activities designed to produce a profit through creatively stimulating and satisfying the needs and/or wants of a selected segement of the market." These activities are to begin prior to production and incorporate; consumer research, product mix, product positioning, new product concepts, financial and promotional planning, the marketing plan, packaging and marketing support materials, advertising, public relations and promotion, the sales and distribution plan and performance evaluations. Cimino and Filice stressed product positioning in order to enable the consumer to differentiate one wine from another within the same category.

Total market decisions for winegrowers revolve around two questions; which class of customers will be targeted and what is the competitive enviroment? The marketing plan then can be divided into four major decision areas called the marketing mix (Figure Six). The decision areas center around product, price, promotion, and place. The decisions in one area must complement those of another inorder to fully intergrate the marketing plan.

In Arizona the initial efforts at product definition will center around the uniqueness of Arizona wines. Small operators will focus on the premium class inorder to generate the returns necessary for long term economic viability. Communication of this position throughout the networks of distribution will ultimately reach the consumer. Consistent quality will be vital to early success. Winer (1984) stated: "It is the marketplace that determines a product's position. It is therefore the test of the marketer and advertiser to utilize the consumer's perception of the product to best achieve the sales objective both in the short and long term."

Small, premium wineries must devise strategies geared toward specific sub-divisions of the total market, rather than higher shares of the larger primary market. Sub-divisions upon which targeting could be based include sex, age, socio-economic patterns as well as localized markets and segmentation by taste appeal.

Figure 6. Marketing Matrix For Marketing Plan.



Source: Downey and Erickson, 1987.

The first wines produced in Arizona will be considered a specialty, with little price competition and a relatively good profit position. Over time as competition discovers the opportunity and enters the market, the wines will be viewed as a commodity. Commodity markets are usually highly competitive, low-profit markets (Downey and Erickson, 1987). Firms contemplating entry into the Arizona market would benefit from producing wines that they deem profitable both during the short term and the long term growth cycle of the Arizona industry.

Product decisions determine what types of wines to offer. For small operators the wines selected for the mix should complement each other technically, in the distribution channels and with consumers, to take full advantage of marketing efficiencies. The mix of red and white wines, and the amount of sweet, semi-sweet, and dry wines, constitute the major product decisions for winegrowers. These decisions are followed closely by what varieties will be used to achieve the desired mix.

Product definition was identified as a critical factor at a wine marketing seminar at the University of San Francisco (Cole 1983). Small premium companies where found to do well when highly focused. The need to specialize in the production of a few fine wines was stressed for small wineries. The optimal marketing strategy was to be at the top of the pyramid among wine products segmented by price,

with low-priced jug wines at the base and high-priced wines at the top.

Pricing strategies are based on actions by competitors, the responses of the consumers and considerations relating to costs of inputs. Pricing decisions will be critical to marketing success, since it influences the total revenue generated by the firm. Lower prices produce less income but usually result in more rapid inventory turn-over. Increased prices can result in slower sales but a better profit margin. The types of wines produced can help determine the pricing strategy. White wines often are sold when they are young and fresh, they should not be stored for extended periods. Red wines mature with age and can be held if sales lag.

Pricing was viewed by Cole as the lifestream of the wine business. "Marketing share is determined by percentage of sales within a particular price-range and the price of a bottle determines its competition and its consumer and therefore, the marketing strategy. Above all, the price must incorporate all costs incurred in production, distribution and promotion, including a margin of profit in line with production capacity." By far the most vital aspect of any marketing program according to Cole, is the quality and content of a winery's public image. "There is no better reputation than that built by word-of-mouth, and no better

way to achieve it than through featuring consistently good wine in wine tastings." (Appendix E and F)

Promotional activities in the wine industry are designed to accomplish one task; sell wine. The marketing strategy for wine is essentially a communication process intended to modify customer behavior toward a positive buying decision. The promotional mix is usually a combination of advertising, personal selling efforts, general publicity, and a sales support program. The particular mix for an individual firm will depend on their product definition, price and method of distribution.

On packaging and point-of-sale materials the message from wine marketers according to Cole was consistent: "Make it damn good or don't make it at all." Hairing (1986) noted that; "Studies indicate the greater the number and quality of wine displays, the more wine is sold. Because less than half the wine purchases in a wine or liquor store are planned - less than 25% in food stores - effective merchandising and selling should lead to increased impulse purchases....application of merchandising techniques has been shown to increase the wine sales of individual stores by 18 to 37%."

Place decisions concentrate on the manner and avenues of distribution that will maximize sales and profits. State farm winery bills that authorize on-premise, retail sales, offer unique opportunities for winegrowers to

sell directly to the consumer. A mix of retail sales and wholesale distribution is the norm for the wine industry. Since retail sales generate higher profits, small operators would benefit from concentrating on retail sales.

Gomberg (1986) reported that the winery tasting room was the gateway to future industry expansion. "Tasting rooms represent a major promotional instrument, particulary for small and medium-sized wineries, upon which success or failure many very well depend. Well-funded, well equipped and well managed tasting rooms can be major centers of profit. Plus, they provide an incomparable vehicle for sampling the public, for establishing person-to-person contact with customers, thus laying the foundation for consumer loyalty. No independently-owned and operated retail store can match this kind of direct contact with visitors to the winery itself."

Arizona

The marketing plan for Arizona premium wineries in the author's view should be predicated on drawing visitors to the on-site winery retail room. Direct retail sales can produce the largest profit margins. Wineries could be located and designed with retail sales in mind. Personel engaging in tours and tastings could be trained in sales techniques in order to maximize retail income. The key to marketing success will be repeat sales.

The wholesale trade will also be vital to the interests of the Arizona wine industry. Wines served in prestiges restuarants and resorts lend an aura of legitamacy to the trade which is especially welcomed in the initial stages of development. Many of the repeat customers will buy their wines in local grocery stores if they are available. There is a built in advantage for local wineries in that the can cultivate contacts with store managers and the consumer more readily that most competing, out-of-state concerns. These advantages must be exploited if the industry is to pass out of the novelty stage.

The primary consideration in marketing wine ultimately resides in the bottle. There is no substitution for quality. Good quality originates in the vineyards, with the choice of grapes and their care. It is said that the vines require the master's shadow as much as sunshine.

The same care must permeate every aspect of the vinification process, bottling and labeling. If the winegrower is expecting a high price for his wines, he must set a high standard of workmanship and create the perception of value. Cleanliness, order, aesthetics, professionalism, are details that have subtle influences on the consumer's taste preferences. They are details that can make or break a small winery.

The marketing plan should appeal to the chauvinistic

pride that Arizonans have in their state. Wine made in Arizona for Arizona is a natural ploy and one that will enable new, farm wineries to compete with established out-of-state firms. Local micro-climates, soils, history, and personalities should be woven with classical cultivars, viticultural practices and fermentation techniques to create an indigenous product. The process should be documented, told and retold to generate the same enthusiasm for the end produce that went into creating it.

CHAPTER FIVE

ADJUSTED INCOMES AND FINANCIAL ANALYSIS

Net present value analysis and internal rate of return evaluation are based on the adjusted incomes developed from the enterprise budgets presented in Chapter Three. The formula for adjusted income takes the form:

AI = NI -(T * (NI - D - I) - TP - M)

Where;

AI = Adjusted Income

NI = Net Income

T = Tax Rate

D = Depreciation

I = Interest Payment

TP = Total Loan Payment

M = Margin Of Owner Equity

The net income is the "net returns above cost shown" line on the enterprise budgets, minus interest expenses. The assumed tax rate for this exercise is the 15% individual rate under the 1986 Tax Reform Act. No investment tax credits are included.

Depreciation is based on the modified accelerated cost recovery system (MACRS) provided for in the 1986 law.

Under the MACRS most farm assets are written off in seven years. Long term capital improvements are depreciated over twenty years. The double (200%) declining balance depreciation method is used for property with a class life of three to ten years. For property in the fifteen to twenty year class, the 150% declining balance method is employed. All classes use a half-year convention, this treats all property as placed in service or disposed of, on the mid-point of that tax year. The depreciation schedules for the various vineyards and wineries are provided in tables 30 and 31.

There are multiple methods for financing a farming enterprise. The primary variable is the mixture of equity and borrowed capital. In this study a development loan is assumed to have been secured to cover the establishment period. The loan is for 75% of the needed investment capital, the required margin of owner equity is 25%. During the first seven years of the operation no payment is made on the loan, interest accrues and becomes part of the princple. In year eight interest and principle payments commence. The loan is paid off over ten years or by the end of the seventeenth year of operation. The interest rate on the loan is varied from 10% to 12% as part of the analysis.

Each adjusted income stream is evaluated on the basis of projected annual income and then under conditions where the enterprise is sold in the twentieth year of

Years One Through Ten Shown Above.

operation. The purpose of including the sale of the business is to fully evaluate the overall profitability of each enterprise.

The valuation of the vineyards and wineries at year twenty is based on the income approach of real estate appraisal. Under this procedure anticipated income, to be derived from ownership of vineyards and wineries, is converted into a value estimate. The estimation of the future value of the property is calculated using the following equation:

$$V = (I/R + I20) - ((I/R + I20 - B) * T)$$

Where;

V = The Market Value

I = The Annual Net Income

R = The Market Capitalization Rate

I20 = The Net Income in Year Twenty

B = The Basis (fixed ownership costs minus interest, insurance and taxes)

T = The Tax Rate

The assumed capitalization rate or required rate of return is 10%. Once the apprasial is complete the value is substituted for the expected income in year twenty on the enterprise budget and becomes incorporated into the adjusted income. Net present value and internal rate of return analysis is conducted in each case on both the adjusted budget before sale of the property and after with the

interest rate for borrowed capital pegged at 10%, 11% and 12%.

Vineyard Analysis

Adjusted incomes are developed for twenty acre vineyards, fifty acre vineyards and one hundred acre vineyards. Appendix G, H, and I, illustrate the adjusted incomes with the price of fruit at $800 a ton. The price received from the sale of fruit was then varied from $800 a ton, to $900 a ton and finally $1000 a ton. A list of all the various adjusted incomes for vineyard analysis is provided in Appendix J.

Net present value and internal rate of return results for vineyards are displayed in table 32. The twenty acre vineyard has a negative net present value under most scenarios which suggests that a 10% required rate of return is unrealistic at this level of production given the assumptions employed for this study. The best results occur at $1000 a ton income from the sale of the fruit coupled with the sale of the enterprise. A 10.07% internal rate of return can be achieved when interest rates are held at 10%.

A grapegrower operating at this level may improve his return by substituting labor for capital inputs or utilizing alternative financing procedures. If the owner is drawing an income as the operator of the vineyard then the results would improve. A lower required rate of return would

also have a favorable impact on the financial analysis.

The fifty and one-hundred acre vineyards display some economies of size. Most of the expensive field machinery used in the twenty acre vineyard is the same utilized by the fifty acre operation. In going to one-hundred acres from fifty acres, the expenditures for machinery and equipment do not double. This represents the most significant variable input if land is assumed to have been purchased in all scenarios.

The net present value for the fifty acre vineyard turns positive when the price of fruit is $900 a ton, interest rates are 10% and the enterprise is sold. The net present value remains negative when calculated solely on the sale of grapes. A 10.58% internal rate of return is achieved on the income from grapes when the interest rate is held to 10% and the price for the grapes is $1000 a ton. The internal rate of return calculated on the income, combined with the sale of the property, achieves a high of 14.62%. Modifications in the assumptions for financing or required return could generate more favorable results.

The one-hundred acre vineyard has a positive net present value in cases where the price of grapes is $900 a ton and the interest rate is held to 11%, and where the price received for the grapes is $1000 a ton. When the price of grapes reaches $1000 a ton the internal rate of return on the income from grapes sold, ranges for 16.83% to

16.07%. The best internal rate of return is 19.47% when the property is sold with a price of $1000 a ton and interest rates held to 10%.

Winery Analysis

Adjusted income streams were developed for twelve thousand gallon, thirty thousand gallon and sixty thousand gallon wineries. Appendix K, L, and M, illustrate the adjusted incomes for wineries where the price of grapes is $800 a ton. The cost of grapes, purchased by the wineries, was then varied from $800 to $900 and then $1000 a ton. Interest rates for borrowed capital varied from 10% to 12%. The adjusted incomes were also evaluated under conditions where the wineries suffered a 10% loss of total receipts and where they gained a 10% increase in total receipts. Changes in total receipts could arise from changes in the sales ratio between retail and wholesale sales or in changes in the prices of the wines. All of the adjusted incomes for wineries are included in Appendix N. Financial analysis is provided in Table 33.

The net present value remains positive from the sale of wine for the twelve thousand gallon winery only when a ten percent increase in receipts is achieved and interest rates and grape prices remain favorable. A ten percent loss of receipts results in a negative net present value for all

scenarios. A 4.58% internal rate of return can be gained when receipts are not adjusted, the price of grapes is $800 a ton, interest rates are 10% and the property is sold at the end of twenty years. A high of 16.61% internal rate of return is achieved under the most favorable conditions. As in the case of small vineyards, the small wineries may be required to rely on increased labor inputs, owner labor and creative finacing to achieve success.

The thirty thousand gallon winery has negative net present values under all conditions when a ten percent loss of receipts occurs. Positive results occur under unadjusted receipts when the price of grapes is held below $1000 a ton and the business is sold. The internal rate of return hits a high of 14.17%. When receipts rise, positive net present values are attained for both income from the sale of wine, and with the sale of the property added. The internal rate of return varies from 8.61% to 22.51%. This result implies that higher receipts from increased on premises, retail sales will be crucial to the success of small wineries.

Some economy of size is displayed by going to a sixty thousand gallon winery. Much of the bottling and labeling equipment is the same as the thirty thousand gallon winery but it operates at a more efficient rate in a larger winery. The same is true for pumps, hoses, presses, and filtering equipment.

A positive net present value can be achieved when

receipts are down, if the interest rate is limited to 10%, the price of grapes remains at $800 a ton and the property is sold. A rise in receipts can produce internal rates of return in the 16.13% to 28.28% range. Unadjusted receipts give positive net present values when the price of grapes is held to $800. Most scenarios that include the sale of the enterprise in the unadjusted cases result in positive net present values, with the internal rates of return between 19.11% and 11.95%.

Vineyard and Winery Analysis

Each vineyard enterprise budget and winery enterprise budget was combined with their appropriate sized counterparts to establish new budgets for the evaluation of joint vineyard/winery ventures. The twenty acre vineyards were combined with the twelve thousand gallon wineries, the fifty acre vineyards were combined with the thirty thousand gallon wineries and the one-hundred acre vineyards were combined with the sixty thousand gallon wineries.

A lag of two years was introduced before the wineries were constructed to reflect the development time in establishing vineyards. Under the previous winery budgets, the fruit was purchased and the wineries were filled to capacity immediately. In the combined budgets, the wineries are filled as production increases in the vineyards. Income from sale of wine is adjusted to shown the additional lag

associated with the vineyards' development. Since the vineyard is part of the winery no cost of fruit is incorporated into the study.

The resulting vineyard/winery depreciation schedules are contained in Table 34. The assumptions for financing the winegrowing operations are the same as in the vineyard and winery cases. The resulting adjusted incomes are set out in Appendix O, P, and Q.

Adjusted incomes are also developed for situations where there is a 10% decrease in receipts and a 10% increase. All the adjusted incomes for combined vineyards and wineries are listed in Appendix R. The results of the net present value analysis and internal rate of return analysis are presented in Table 35.

The twenty acre vineyard/twelve thousand gallon winery has a negative net present value unless receipts rise 10%. Given a ten percent increase in receipts and the sale of the enterprise, the best internal rate of return it can achieve is 10.48%.

The fifty acre vineyard/thirty thousand gallon winery also has a negative net present vlaue for all cases where the analysis is for income derived from the sale of wine and receipts are normal or 10% below normal. A positive net present value results when the property is sold, for cases where the receipts remain unchanged and where receipts

rise. The best internal rates of return occur where the interest rates remain at ten percent.

This implies that small, premium winegrowers must rely on creative alternative methods of marshalling their inputs and marketing their wines. Quality and value in the finished wines will be imperative for success which most likely will be predicated on higher prices and retail sales.

The one-hundred acre vineyard/sixty thousand gallon winery displays positive net present values for all cases, including those where a ten percent decrease in receipts occur. The internal rate of return varies under the analysis on income from the sale of wine, with the receipts unchanged, from 13.99% to 12.37%. At this level of production, retail sales are less crucial than in the case of smaller wineries. The challenge for larger premium wineries will be to set up an efficient distribution network to insure an orderly turnover of inventory. Currently no Arizona winery has achieved this level of production or market penetration.

CHAPTER SIX

SUMMARY AND CONCLUSIONS

In the mid 1960's the United States entered into an unprecedented wine boom based on premium grape varieties such as Chardonnay, Cabernet Sauvignon and Pinot Noir. Between 1975 and 1985, 720 new wineries opened with forty one states possessing at least one bonded winery. Half the winery growth occurred outside of California including four bonded wineries in Arizona.

Arizona's first commercial plantings of fine wine grapes occurred in the early 1980's, near Sonoita, in southeastern Arizona. Eco-niches were located at altitudes above 4,000 feet that combined the correct soils, climate and water availability to ripen classic vitis vinifera wine grapes to maturity, with excellent pH balances and good sugar and acid levels. The wines vinified from these vineyards have been of award winning quality.

The native industry produced an estimated .002% of Arizona's aggregate demand for wine in 1986. The balance was imported. Only 150 acres of fine wine grapes were available, with most of the acreage just reaching the bearing stage. Plantings in 1987 are expected to double

Arizona's total wine grape acreage. These vineyards will take seven years to reach full maturity.

Favorable demographics and population growth is forecasted by this study to push total wine consumption in Arizona from 9,000,000 gallons in 1987 to 33,000,000 gallons by the year 2015. This work predicts that if Arizona winegrowers are able to capture 10% of their state's wine consumption by the year 2015, as many as 130 small wineries and 5500 acres of grapes will be needed.

The bulk of this study examines the costs and returns of small, premium quality vineyards, wineries, and joint vineyards and wineries in Arizona. The central assumption of this thesis is that high grade materials, equipment, and labor must be employed to produce the highest calibre of grapes and wine. High standards of quality will be essential for small vineyards and wineries in Arizona to capture and retain market shares. Diseconomies of size will force them to compete on the premium level.

The results of this study indicate that grape growing and wine making are capital intensive endeavors. Large capital expenditures are required in the early years of the operations, while the benefits may accrue over as many as forty years. A long planning horizon is necessary to achieve a positive net present value. Even a small twenty acre vineyard can require several hundred thousand dollars

before required internal rates of return are generated. The costs of a small winery can easily double the expenditures necessary for a supporting vineyard, with the same long term investment outlook.

This study indicates that small, premium vineyards, wineries and joint vineyards and wineries can yield high rates of return and positive net present values under ideal conditions in Arizona. Economies of size were found to favor the returns generated from the largest sized operations. In going from a twenty acre vineyard to a one-hundred acre vineyard, and from a twelve thousand gallon capacity winery to a sixty thousand gallon capacity winery increased efficiencies are gained in employment of equipment and machinery.

The larger the vineyard or winery, the less sensitive the enterprise is to the price of grapes. the larger the joint vineyard and winery, the less sensitive the firm becomes to fluctuations in income. These findings are illustrated in Tables 36, 37, and 38.

Smaller vineyards and wineries in Arizona may have to substitute labor for capital, alter their financing or lower their expected return under the assumptions employed by this study inorder to gain more favorable results. The advantage smaller operations have will be in their control of inputs and output, and especially in marketing on a

Figure 7. Internal Rate Of Return For Vineyards.

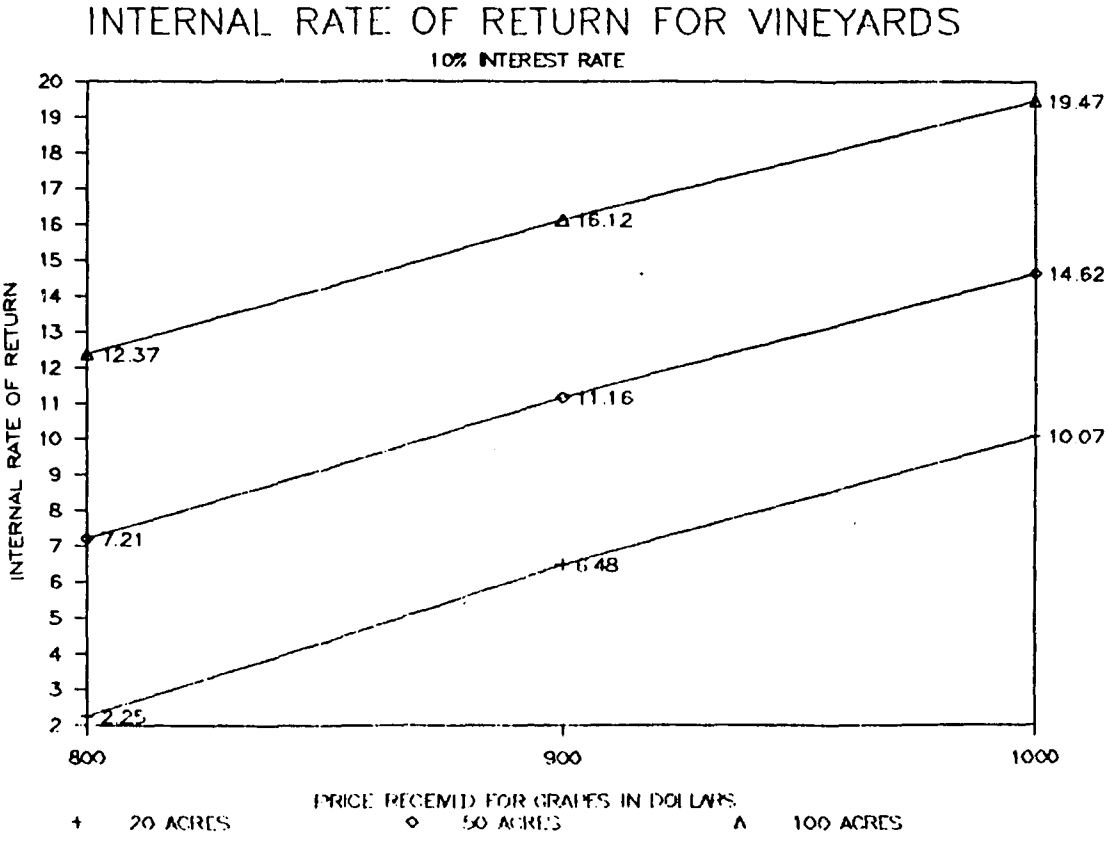

Figure 8. Internal Rate Of Return For Wineries.

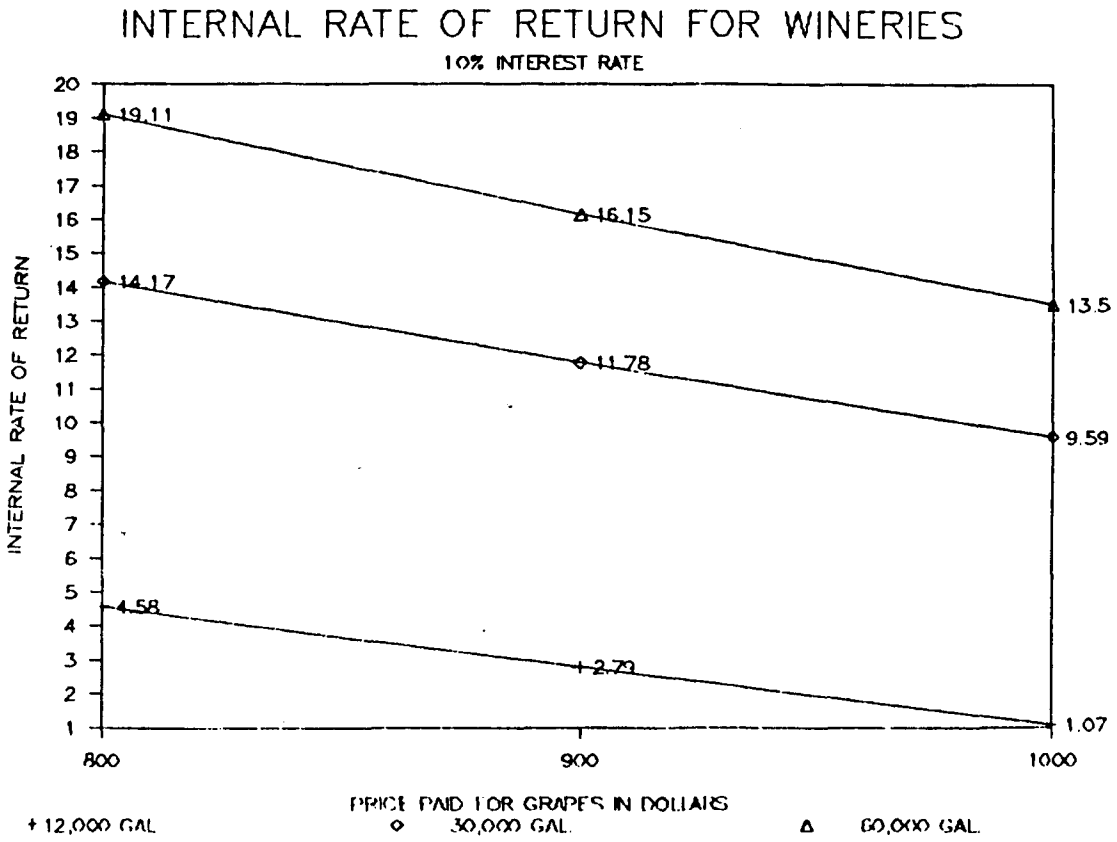

Figure 9. Internal Rate Of Return For Combined Vineyards/Wineries.

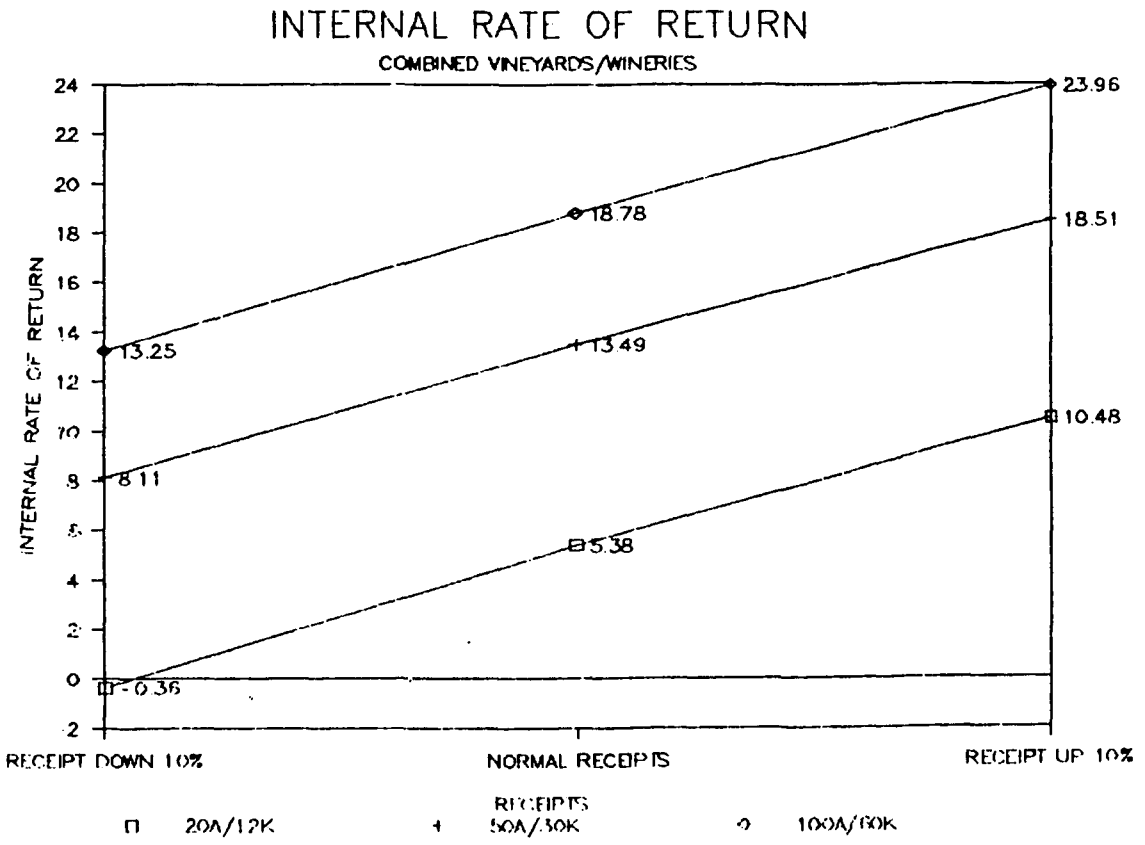

retail level. Larger firms will be pressed into expanding their marketing efforts into the wholesale realm with a corresponding loss of direct operator control, however they will be less sensitive to variations in the market place.

It appears that Arizona has a positive future as a wine producing state. The scope of this study has been confined primarily to the exclusive end of the wine industry, with a focus in southeastern Arizona and on small farm wineries. Favorable land costs, labor costs, climates, and growth in demand would seem to suggest that intermediate sized vineyards and wineries producing good table wines would also be successful in numerous regions of Arizona. The key to the future of the wine industry in Arizona lays not in the vineyards or wineries, where commercial quality standards have been achieved, but in the marketplace where consistent demand must be established.

APPENDIX A

The following is the wording of the 1982 Arizona Domestic Farm Winery Bill, from Arizona Revised Statutes, Annotated, 1986, Supplementary Pamphlet, Vol 2 Titles 1 to 8, page 189.

4-205.04 Domestic farm winery license; regulatory provisions.

A. The board may issue a domestic farm winery license to any domestic farm winery. The licensee may not transfer the domestic farm license from person to person or from location to location.

B. An applicant for a domestic farm winery license shall, at the time of filing the application for the license, accompany the application with the license fee. Persons holding a domestic farm winery license shall report annually at the end of each fiscal year, at such time and in such manner as the board may prescribe, the amount of wine manufactured by them during the fiscal year. If the total amount of wine manufactured during the year exceeds the amount permitted annually by the license, the licensee shall apply for a vintner's license.

C. Notwithstanding any other statute, the holder of a domestic farm winery license may sell wine produced or

manufactured on the premises in the original container for consumption off the premises and may make sales and deliveries of wine to persons licensed to sell wine under this title. A holder of a domestic farm winery license may serve wine produced or manufactured on the premises for the purpose of sampling the wine.

D. Not withstanding 4-101, paragraph 8, the superintendent may allow a percentage of out-of-state agricultural products greater than twenty-five per cent in wine manufactured or produced by a domestic farm winery if the domestic farm winery can demonstrate to the satisfaction of the superintendent that sufficient in-state agricultural products are not available because of an unexpected failure of suitable in-state crops due to natural causes. The exemption shall remain in effect only for the period of time during which such shortages actually exist.

E. The superintendent shall prescribe rules and regulations in order to administer this section

APPENDIX B

The following was wording for the proposed rules for the Sonoita viticultural area from the Federal Register, Vol. 49, No 96, May 16, 1984.

ESTABLISHMENT OF SONOITA VITICULTURAL AREA

AGENCY: Bureau of Alcohol, Tobacco and Firarms, Department of the Treasury.

ACTION: Notice of proposed rulemaking.

SUMMARY: The Bureau of Alcohol, and Firearms (ATF) is considering the establishment of a viticultural area in Arizona to be known as "Sonoita". This proposal is the result of a petition from Mr. Blake Brophy, a grape grower in the area. The establishment of viticultural areas and the subsequent use of viticultural area names in wine labeling and advertising will enable winemakers to label wines more precisely and will help consumers to better identify the wines they purchase.

SUPPLEMENTARY INFORMATION

BACKGROUND: ATF regulations in 27 CFR Part 4 provide for the establishment of definite viticultural areas. The regulations also allow the name of an approved viticultural area to be used as an appellation of origin on wine labels and in wine advertisements.

Part 9 of 27 CFR provides for the listing of approved American viticultural areas, the names of which may be used as appellations of origin.

Section 4.25a(e)(1), title 27, CFR, defines an American viticultural area as a delimited grape-growing region distinguishable by geographical features. Section 4.25a(e)(2) outlines the procedure for proposing an American viticultural area. Any interested person may petition ATF to establish a grape-growing region as a viticultural area. The petition should include-

(a) Evidence that the name of the proposed viticultral area is locally and/or nationally known as referring to the area specified in the petition;

(b) Historical or current evidence that the boundaries of the viticultural area are as specified in the petition;

(c) Evidence relating to the geographical features (climate, soil, elevation, physical features, etc.) which distinguish the viticultural features of the proposed area from surrounding areas;

(d) A description of the specific boundaries of the viticultural area, based on features which can be found on United States Geological Survey (U.S.G.S.) maps of the largest applicable scale; and

(e) A copy of the appropriate U.S.G.S. map(s) with the boundaries prominently marked.

PETITION: ATF has received a petition from Mr. A. Blake Brophy of the Babocamari Ranch Company, proposing an area near Sonoita, Arizona, as a viticultural area to be known as "Sonoita." The area contains about 325 square miles. It is located in extreme southern Arizona, near the Mexican border. There are about 40 acres of grapes currently planted in the proposed area. the petitioner states that plans call for 360 additional acres to be planted. A winery is currently under construction. Soils in the area that are suitable for wine-grape production include White House-Bernardino-Hathaway and the Caralumpi-Hathaway associations. Grapes are being grown on the floor of the proposed viticultural area at altitudes of between 4,500 and 5,000 feet.

The petitioner claims that the proposed viticultural area is known by the name "Sonoita" and is associated with grape growing for the following reasons;

(a) "Sonoita" is the name of the only viable community in the area. (The town of Sonoita is centrally located within the proposed viticultural area.)

(b) Historically the name "Sonoita" is derived from a visita established in 1691 by the missionary-explorer, Father Eusebio Francisco Kino. At that time, the name given to this small settlement of Sobaipuri Indians was "Los Santos Reyes de Sonoita."

(c) Since 1975, the Babocamari Ranch Company has been cooperating with the University of Arizona in the growing of vitis vinifera grapes in the area and in the making of wine from those grapes. These efforts have been described in an article in The American Journal of Enology and Viticulture, Vol. 32 No. 4, pp. 209-296, entitled "The Use of Soils for the Delineation of Viticultural Zones in the Four Corners Region". This article calls the proposed area "Sonoita": for example: "Other sites such as Sonoita... produce much better fruit than expected" (p.291).

The Petitioner claims that the proposed viticultural area is distinguished geographically from the surrounding areas for the following reasons:

(1) Topographically, the area is separated from the surrounding areas by three major mountain ranges: the Santa Rita Mountains, the Huachuca Mountains, and the Whetstone Mountains. These mountains rise from 2,500 to 4,500 feet above the floor of the viticultural area.

(2) The "old timers" used to call the area "Sonoita Valley", because it resembles a valley in appearance. But geologically, the area is technically a basin rather than a valley, because it comprises the headwaters for three distinct drainages; Sonoita Creek to the south, Cienega Creek to the north, and the Babocamari River to the east. (In technical geological terms, a "valley" would comprise only a single drainage.)

(3) The most obvious geographical distinction to the area is that in its native state, it is classified as "high desert grassland", while the surrounding terrain is either mountain or woody shrub desert. (See Humphrey, Robert R., The Desert Grassland, University of Arizona Press.)

The boundaries of the proposed viticultural area may be found on seven U.S.G.S. quardrangle maps in the 7.5 minute series: Benson, Fort Huachuca, Sunnyside, Elgin, Lochiel, Mount Wrightson, and the Empire Mountains.

REGULATORY FLEXIBILITY ACT: The provisions of the Regulatory Flexibility Act relating to an initial and final regulatory flexibility analysis (5 U.S.C.603,604) are not applicable to this proposal because the notice of proposal rulemaking, if promulgated as a final rule, will not have a significant economic impact on a substantial number of small entities. The proposal is not expected to have significant secondary or incidental effects on a substantial number of small entities, because the value of the proposed viticultural area designation is intangible and subject to influence by unrelated factors. Further, the proposal will not impose, or otherwise cause a significant increase in the reporting, recordkeeping, or other compliance burdens on a substantial number of small entities.

PUBLIC PARTICIPATION-WRITTEN COMMENTS: ATF requests comments concerning this proposed viticultural area from all

interested persons.

Futhermore, while this document proposes possible boundaries for the Sonoita viticultural area, comments concerning other possible boundaries for this viticultural area will be given consideration.

Comments received before the closing date will be carefully considered. Comments received after the closing date and too late for consideration will be treated as possible suggestions for future ATF action.

ATF will not recognize any material or comments as confidential. Comments may be disclosed to the public. Any material which the commentor considers to be confidential or inappropriate for disclosure to the public should not be included in the comment. The name of the persons submitting is not exempt from disclosure.

PART 9-AMERICAN VITICULTURAL AREAS: Sonoita.

(a) Name. The name of the viticultural area described in this section is "Sonoita".

(b) Approved maps. The appropriate maps for determining the boundaries of Sonoita viticultural area are seven U.S.G.S maps. They are titled:

(1)Benson Quadrangle, 7.5 minute series, 1958.

(2) Fort Huachuca Quadrangle, 7.5 minute series, 1958.

(3) Elgin Quadrangle, 7.5 minute series, 1958.

(4) Lochiel Quadrangle, 7.5 minute series, 1958.

(5) Mount Wrightson Quadrangle, 7.5 minute series, 1958.

(6) Sunnyside Quadrangle, 7.5 minute series, 1958.

(7) Empire Mountains Quadrangle, 7.5 minute series, 1958.

(c) Boundary-(1) General. The Sonoita viticultural area is located in Arizona. The starting point of the following description is the summit of Mount Wrightson (9,543 feet) in the Santa Rita Mountains.

(2) Boundary Description-(i) From the starting point southeastward in a straight line for approximately 24 miles, to the summit of Lookout Knob (6,171 feet) in the Canelo Hills.

(ii) From there in a straignt line eastward for approximately 10 miles, to the summit of Huachuca Mountains.

(iii) From there north-northwestward for approximately 21 miles in a straight line to the summit of Granite Peak (7,413 feet) in the Whetstone Mountains.

(iv) From there west-southwestward in a straight line for approximately 26 miles to the summit of Mount Wrightson (the point of beginning).

APPENDIX C

Check List of Decisions to be Completed Prior to Building the Winery.

I. BUSINESS PLAN
  A. Type of Product Produced
    1. Table Wines
    2. Desert Wines
    3. Sparkling Wines
    4. Brandy
    5. Special Natural
    6. Other
  B. Volume of Product Produced
  C. Price Level of Product Produced
    1. Main Product Line
    2. Secondary Product Line
    3. Private Labels
    4. Bulk
  D. Quality Level of Product Produced
  E. Marketing Plan
II. SOURCE OF RAW MATERIAL
  A. Is the source of raw material consistent with the expected company inage above?
  B. Can the winery be built reasonably close to the vineyard?
III. SOURCE OF CAPITAL
  A. Is the source of capital consistent with the expected company inage above?
  B. Is the source of capital consistent with projected profit picture?
  C. Can the source of capital accept expansion, at least 100% beyond expectations?
IV. PERSONNEL
  A. Is the personnel plan consistent with the expected company image above?
  B. Professionalism.

SOURCE: Peterson (1975).

APPENDIX E

Sam Sebastiani, past-president of the family winery, commented on the American wine industry at the 1985 Wine Industry Technical Symposium (Sebastiani 1985). He stated that the wine business was in transition to maturity and five major changes were effecting the competitive enviroment.

"1. Slowing growth means more competition for market share. The competition begins to attack the market share of others. The biggest mistake that I see the new small wineries making is that they are trying to become national brands....there is a need to focus your brand....attack specific markets and specific segments of the market.

2. Transition to industry maturity requires that wineries increasingly sell to experienced, repeat buyers. Merely telling the customer that your wine is better than the other guy's is not marketing. That is not brand awareness. That's not positioning.

3. In the transition to industry maturity, competition often shifts toward greater emphasis on cost and service. Have you focused your brand so that you can control cost and service?

4. The transition to industry maturity is marked by the emergence of significant international competition. It

has happened in dozens of industries....The garment, the automobile and tractor and calculator and computer industries and everyone in this room clearly understands the degree to which it has happened in the wine industry.

5 Transition to industry maturity forces distributor margins to fall, but their power increases. For the same reason that our profits are often depressed, distributor margins also are squeezed. Some distributors drop out of the business and when this happens it suddenly becomes harder to find and hold on to a distributor.

I don't know what the next 10 or 15 years holds for the California wine industry, but looking back, there have been only four years of double-digit growth, 1969-1972. The last three years, 1982-1984 represent the first time in those 25 years that we have had three consecutive years of below 3% growth.

If I had to guess, I would think that we should develop a strategy for even smaller increments of growth. Slow, steady, solid growth. A kind of growth that is not dependent upon fads and trendiness....but a growth that encourages the use of wine as a gracious part of everyday American life."

APPENDIX F

Elliott Fine, president of his own marketing company and former president of Paul Masson offered "Ten Commandments" for marketing wine at the 11th Wine Industry Technical Symposium Marketing Sessions (Wines and Vines, March 1985).

1. "Thow Shalt Focus On The Consumer." Producers must make what consumers want.
2. "Thou Shalt Not Pay Too Much Attention To The Numbers." Industry figures have little relevance for small wineries with miniscule market shares. Numbers are "nothing more than a weather report."
3. "Thou Shalt Not Be Afraid Of The Giants." Brands are built by entrepreneurs, not corporations.
4. "Thou Shalt Have A Plan." It must be specific with close attention paid to price.
5. "Thy Products Will Fit The System." Wholesaler needs must be identified and satisfied.
6. "Thou Shalt Be Different." Product differentiation is essential to sales.
7. "Thou Shalt Not Introduce Another Me-Too Product." Focus must be on a few products done well, rather than multiple efforts.

8. "Remember The Paradox Of The Wholesalers." There are half as many wholesalers today as there were twenty years ago, and up to three times as many brands. Suppliers must give wholesalers support in the form of personnel, advertising, and sales materials.

9. "Thou Shalt Cherish Your Wholesaler." People and support are necessary to nourish a good working relationship with wholesalers.

10. "Thou Shalt Have The Right Tools." Wines that can produce profits are the key to success.
